Notice

This report has been prepared by the TRADOC Analysis Center-White Sands Missile Range under the sponsorship of US Army Models and Simulation Office, ODCSOPS, ATTN: DAMO-ZS 400 Army Pentagon Washington, DC 20310-0400. This report documents analysis based on best available data, scenarios, and model versions at the time of the analysis. The findings in this report have not been reviewed by the US Army Models and Simulation Office and may not be construed as an official US Army position unless so designated by other official documents.

Destruction Notice

Destroy in accordance with the procedures in DOD 5200.22-M, Industrial Security Manual, Section 11-19 or DOD 5200.1-R, Information Security Program Regulation, Chapter IX.

13. ABSTRACT (Maximum 200 words) Prediction of realistic line-of-sight (LOS) conditions has always been an essential aspect of combat simulations. The representation of LOS in areas with surface features (vegetation) has never been extensively examined. However, recent advances in weapons systems, combat simulators, and the evolving mission requirements of the modern Army have demonstrated the need for a more precise understanding of how vegetation impacts LOS prediction. This study will: (1) identify geotypical feature density zones; (2) document typical LOS within each with a field collection effort and; (3) predict future LOS performance. The output of this study will: (1) facilitate the selection of a standard algorithm for LOS which performs effectively in varied feature densities and (2) provide recommendations on how to improve the play of surface features in combat models.

Effects of Vegetation on Line-of-Sight (LOS) for Dismounted Infantry Operations Study Gist

Purpose. This research provides a better understanding of line-of-sight (LOS) in vegetated areas. It also provides equations and parameters for those equations allowing analysts involved in combat simulation to depict dismounted infantry engagements more accurately.

Critical Issues Addressed. Prediction of realistic LOS has always been an essential aspect of combat simulations. The representation of LOS in areas with surface features (vegetation) has never been extensively examined. With recent advances in weapons systems, the increased use of combat simulators, and the evolving mission requirements of the modern Army have demonstrated the requirement for a more precise understanding of how vegetation impacts LOS prediction.

Objectives. Provide analysts with a standard algorithm providing accurate LOS in varied vegetation densities and provide recommendations on how to improve the simulation of LOS in vegetation for combat models.

Principal Findings. Vegetation varies throughout the world and, thus, impacts LOS differently. This research examined vegetation as a function of vegetative biome (a combination of climate and vegetation) and provides algorithms accurately portraying LOS

in different densities and types of vegetation.

Impact/Utility to the Army. Even before the analysis was complete, a major combat simulation, the Combined Arms Support Task Force Evaluation Model (CASTFOREM), was modified to incorporate data and algorithms from this study in order to portray LOS in vegetation more realistically. Ultimately, this work will improve the simulation of dismounted infantry combat in other combat simulations.

Main Assumptions. The field-collected data is representative of the vegetation for each study area. The field-collected data can be extrapolated to areas with similar vegetation, climate, soil, latitude, and elevation.

Principal Limitations. Several world vegetation types had to be omitted from this study. These include areas void or nearly void of vegetation (i.e., desert and tundra), areas inaccessible to the data collection team (i.e., Australia and Siberia) or areas where deployment of troops is unlikely (i.e., the Great Lakes region).

Scope. The scope of this research was limited to collecting visibility data between dismounted infantry units. Since it is unlikely that two units will encounter each other randomly, this work focused on a unit in defense and a unit in attack.

Approach. The approach used in this study included the following steps: identify data collection locations (general geographic areas), select a tactically sound defensive position and a tactical field of view, collect data consisting of how much of a kneeling infantryman is visible as a function of range, and provide a fit to three different types of curves (exponential, field exponential, and pole-zero) representing LOS in vegetation as a function of range.

Study Sponsor. United States (US)
Army Models and Simulation
Organization

Performing Organization and Principal Authors. Mr. Danny C. Champion of the Training and Doctrine Command (TRADOC) Analysis Agency-White Sands Missile Range (TRAC-WSMR), and Mr. Louis A. Fatale and Dr. Paul Krause of the US Army Topographic Engineering Agency (TEC)

Literature Search. A literature search examined documents which: focused on forestry research, included a keyword search of Defense Technical Information Center (DTIC), and included internet searches. Also, modeling and simulation agencies (both US and allied forces) were contacted to determine if any similar work had been conducted.

DTIC Accession Number. DA358645

Start and Completion Dates.

Preface

This study was conducted between the period September 1997 until March 1999. During this period, several organizations generously provided funding to this work. They are:

United States (US) Army Modeling and Simulation Organization (AMSO)

US Army Training and Doctrine Command (TRADOC) Analysis Center-
White Sands Missile Range (TRAC-WSMR), NM

US Army Topographic Engineering Center (TEC), Alexandria, VA

US Test and Evaluation Command (TECOM), Yuma Proving Ground, Yuma, AZ

Rapid Force Projection Initiative, Huntsville, AL

Directorate Land Operations Research, Ottawa, Canada

Special thanks go out to the following people from TRAC-WSMR: Ms. Donna Vargas, Mr. Walt Butler, Ms. Lounell Southard, and Mr. Joseph Bebbs of the Brigade Models and Simulation Directorate for allowing time to conduct this study; Mr. Robert Williams of the Technical Reports Office for helping develop the field collection methodology, produce all of the briefing slides, and providing most of the figures for the report; Sergeant First Class (SFC) James Nicholson for assisting in the field collection and providing software support during the analysis; Staff Sergeant (SSG) Raymond Heiskell for helping to develop the data collection methodology, assisting in the data collection, and providing an infantryman's perspective to the work; Sergeant (SGT) David Bliss for spending many thankless hours putting together many of the graphics seen in this report and double checking all of the data; Dr. Kathy Nau for providing constant sanity checks on the analysis; SFC Gus Williams and SSG Patrick Quenga for assisting in the data collection effort; Ms. Donna Johnson for assisting in the data collection effort, developing the software to fit the raw data with exponential and pole-zero curves, and providing significant enhancements to the written report; Ms. Rita Baird, Ms. Gretchen Lindsay, Ms. Soyla Ward, Ms. Jackie Reyes, and Ms. Annaliza Arvizu of the Technical Reports Office, whose patience and tireless effort brought all of this work together into the final report. Finally, the authors would like to thank Mr. Peter Shugart for reviewing the report and making changes that make the report better and not just different.

Special thanks go out to the following people from TEC: Mr. Jeffery Messmore for his work on the original proposal and his continued motivation and support during the long field collection process; Mr. William Clark and Ms. Kathy Flood for their support to the Korea/Yugoslavia analog work; all members of the Information Services and Support Branch, especially Mr. Cedric Key and Ms. Angela Straub for graphics support; and Mr. Paul Cerevich, Mr. Tom Cox, and Mr. Dan Oimoen for their advice and invaluable support in supplying the survey equipment used in this study.

Special thanks also goes out to Dr. James P. Reilly of New Mexico State University for allowing us to borrow surveying equipment during development of the data collection methodology.

The authors' gratitude is also extended to Dr. Arthur N. Strahler and John Wiley and Sons Publishing Company for their generous permission to reproduce graphics and text which played an important role in the development of the study.

Special thanks also goes out to SSG Todd Antal from the Northern Warfare Training Center at Fort Greely, AK, for providing input about arctic infantry operations and for his assistance in selecting sites that were representative of a boreal climate and in the subsequent data collection. Additionally, we wish to thank the following people at the Tropical Test Center, Corozal, Panama: Larry Havrilo (Ch.), Rolando Ayala, Tamara Paredes, Alcibiades Grajales (Sr. and Jr.), Alonso Iglesias, Ricardo Martinez, Dinorah Tijerino, Lloyd Hay, Juventino Serrano, and James Bryan without whose support the tropical analyses of this study could not have been completed.

Special appreciation is also extended to Messrs. Lance Vanderzyl, Acting Director of the Tropic Test Center and Mr. Ruben Hernandez, Optical Development and Integration Branch, Yuma Proving Ground whose unwavering support of the study and foresight regarding tropical environments facilitated the development of a substantially improved final report.

John D'Errico, a retired infantryman from the Dismounted Battlespace Battle Lab, provided an infantry perspective to the field collection at Fort Benning, assisted with the field collection, and provided many of the field supplies used during the course of the study.

Finally, the authors would like to thank Mr. Pierre Ladouceur and Ms. Mary Ellen Campbell, Canadian National Defence Headquarters, Ottawa, Ontario, Canada, for their coordination of the New Brunswick, Canada data collection effort which provided the opportunity for the incorporation of a valuable international site into the study.

Mr. Roy Reynolds was the Director and Colonel (COL) Gary G. Swenson was the Senior Military Analyst of TRAC-WSMR at the time of the publication of this report. Dr. William E. Roper was Director of the Topographic Engineering Center (TEC) at the time of the publication of this report.

Effects of Vegetation on Line-of-Sight (LOS) for Dismounted Infantry Operations

Introduction

The realistic representation of line-of-sight (LOS) is an essential aspect of combat simulations. Until the end of the cold war, combat modeling had focused on large armored forces where the representation of surface features (e.g., vegetation and urban structures) was not of primary importance in the calculation of LOS.

Since 1989, the United States (US) Army has deployed over a dozen times. With the exception of Desert Storm, all of the deployments have focused on smaller operations using dismounted infantry units. Therefore, there is today a new emphasis on the operations of relatively small and rapidly deployable forces and a consequent increased effort to simulate the dynamic combat of dismounted infantry. Additionally, this emphasis is also driven largely by the emergence of Dismounted Interactive Simulation systems where virtual, live, and constructive simulations are combined.

In combat, dismounted soldiers maneuver and fight using surface features for concealment. There is a modeling shortfall in the realistic simulation of LOS in areas containing a high density of surface features.

Background

LOS is, by definition, a point-to-point measure. A sensor and a target are represented by a pair of (x, y, z) coordinates. LOS is defined to exist if there are no obstructions in the straight line between the two points. For this study, assume the target is represented as a two dimensional area with a boundary. The questions to be addressed here are:

- Taking into account the surface features of the terrain, does LOS exist between the sensor and any point on the target?
- When such LOS exists, what percent of the target area is visible?

Over the last 30 years, there has been very little research examining LOS in areas with surface features. Since 1994, the US Army Training and Doctrine (TRADOC) Analysis Center-White Sands Missile Range (TRAC-WSMR) and the Topographic Engineering Center (TEC) have worked together to improve LOS representation for high resolution combat simulations. Unfortunately, this research was limited to areas void of significant surface features (Fort Irwin and Twentynine Palms, CA; Yakima Training Center, WA; and Yuma Proving Grounds, AZ).

Currently, LOS in vegetated areas is generally played using one of the following methods:

- The surface feature completely blocks LOS. With this methodology, surface features are simulated as a solid object. Units can move within the features, but there is no visibility into the feature, out of the feature, or within the feature.
- The surface feature completely blocks LOS with one exception. The user inputs the distance sensors can see into and out of the surface feature. This methodology allows units to deploy just inside a tree line while maintaining LOS to the battlefield. Although based on operational experience and common sense (no one would deliberately take up a position in which the LOS to the region under surveillance does not exist), there is no quantitative basis for this "see-through" distance, which gives units perfect visibility until the "see-through" value is exceeded. From then on, the visibility is governed by the characteristics of the terrain and surface features at the end of the "see-through" distance. If obstructing surface features are present, the visibility goes to zero.
- A probability of LOS is defined for a unit of distance (usually 25 meters) into an area with surface features. For example, if the user input is 0.9 and a sensor is trying to see 75 meters into trees, the probability of LOS is 0.729 ($0.9 \cdot 0.9 \cdot 0.9$). However, the input probability has no quantitative basis.
- A virtual simulator draws all the features between the sensor and the target one at a time in order to play their effects. This can be a time consuming process. Typically, the individual trees are stylized fonts (i.e., they are either all the same tree or there are a small number of different trees) and the number of trees that can be represented in a small area is constrained by the polygon limits of the simulator. The shortfall of this method was emphasized in a 1997 National Imagery and Mapping Agency (NIMA) study examining the requirements for high resolution modeling in which the soldiers who evaluated the database felt the representation of vegetation was not realistic in the NIMA database.

The above examples illustrate the lack of quantitative data to support LOS calculations in models of high resolution dismounted combat in a vegetative environment. A set of quantitative LOS data in areas of high feature density would help modelers portray combat in a more realistic manner. Recent advances in weapon systems, combat simulators, and the evolving mission requirements of the modern Army (i.e., stability and support operations, hostage rescue operations, peacekeeping operations, and low intensity conflict) require a more precise understanding of the impact of vegetation on LOS prediction. TRAC-WSMR and TEC recognized this problem and developed this study to:

- Identify a wide variety of vegetation types with associated climate zones.
- Collect data within each area to determine the percent of target visible when the LOS existed at a given range.
- Provide functions, based on the analysis of the collected data, which will enable the calculation of the percent of target visible using the range of the LOS and the terrain classification.

This report documents these efforts, draws conclusions, and makes recommendations to the modeling and simulation (M&S) community as to the selection of a standard algorithm to depict LOS in varied vegetation densities and how to improve play of surface features in combat models.

Purpose

This research provides a better understanding of LOS in vegetated areas through a set of graphs showing the portion of a target visible in different vegetation types as a function of range. Also provided are tables containing parameters used in equations generating the graphs. All of the graphs and equation parameters are based on empirical data.

Scope

The scope of this research was limited to collecting visibility data between dismounted infantry units. It is unlikely two units in a vegetated area will encounter each other at random. A more common scenario is an attacking unit encountering a defensive position. Therefore, this research focused on the LOS between a unit in a tactically sound defensive position and a unit in attack.

Limitations

Several vegetation types were excluded from this study. These included desert, arctic tundra, and areas inaccessible to the data collectors.

Assumptions

The field collection sites were representative of the vegetation in each study area.

The field-collected data can be extrapolated to areas with similar vegetation types, climate, soil types, latitude, and elevation (in order of importance).

Within a given vegetative zone, it was assumed types and densities of vegetation growing in flat areas are equivalent to vegetation growing on rolling terrain. Therefore, the field collection effort took place in areas where the change in ground elevation was negligible.

Difference Between LOS and Detection

Briefly, LOS is a geometry problem and detection is a physics and physiology problem using LOS and target presented area (the measures collected here) as factors. The current detection model is discussed at length in appendix A. However, in order to gain insight into the details involved in calculating probability of detection, some of the inputs provided by the combat simulation are listed below:

- Target contrast (the ratio of target brightness and background brightness)
- Visible light
- Sky over ground (SOG) ratio (contrast between the sky and the ground)
- Type of sensor (naked eyes, binoculars, night vision devices)
- Atmospheric attenuation effects
- Minimum resolvable contrast
- Whether or not the target is stationary or moving

Figures 1 and 2 illustrate the difference between LOS and detection. Figure 1 depicts three moths on a tree that are fully visible but very difficult to detect. By changing the contrast of the tree (see figure 2), the moths become much easier to detect.

Figure 1. Moths on Tree Bark – Fully Visible, Difficult to Detect

Figure 2. Moths on Tree Bark – Fully Visible, Easy to Detect

Methodology

Introduction

There are four steps to the methodology for this study: (1) the selection of data collection locations (the general geographical area), (2) the selection of site (the defensive positions where data were collected), (3) determination of the tactical considerations of data collection, and (4) determination of how the data would actually be collected.

Geographic Selection for Data Collection

Initially, the locations for data collection were to cover all of the climates in the continental US (CONUS). An analysis of vegetation types located within each climate zone indicated that vegetation varied greatly within each zone. Vegetative biomes, which are related to climate, provided a better method to delineate vegetation types. To provide even better detail about vegetation types, biomes have been divided into sub-biomes. Figure 3 shows a vegetative sub-biome map for the entire world.

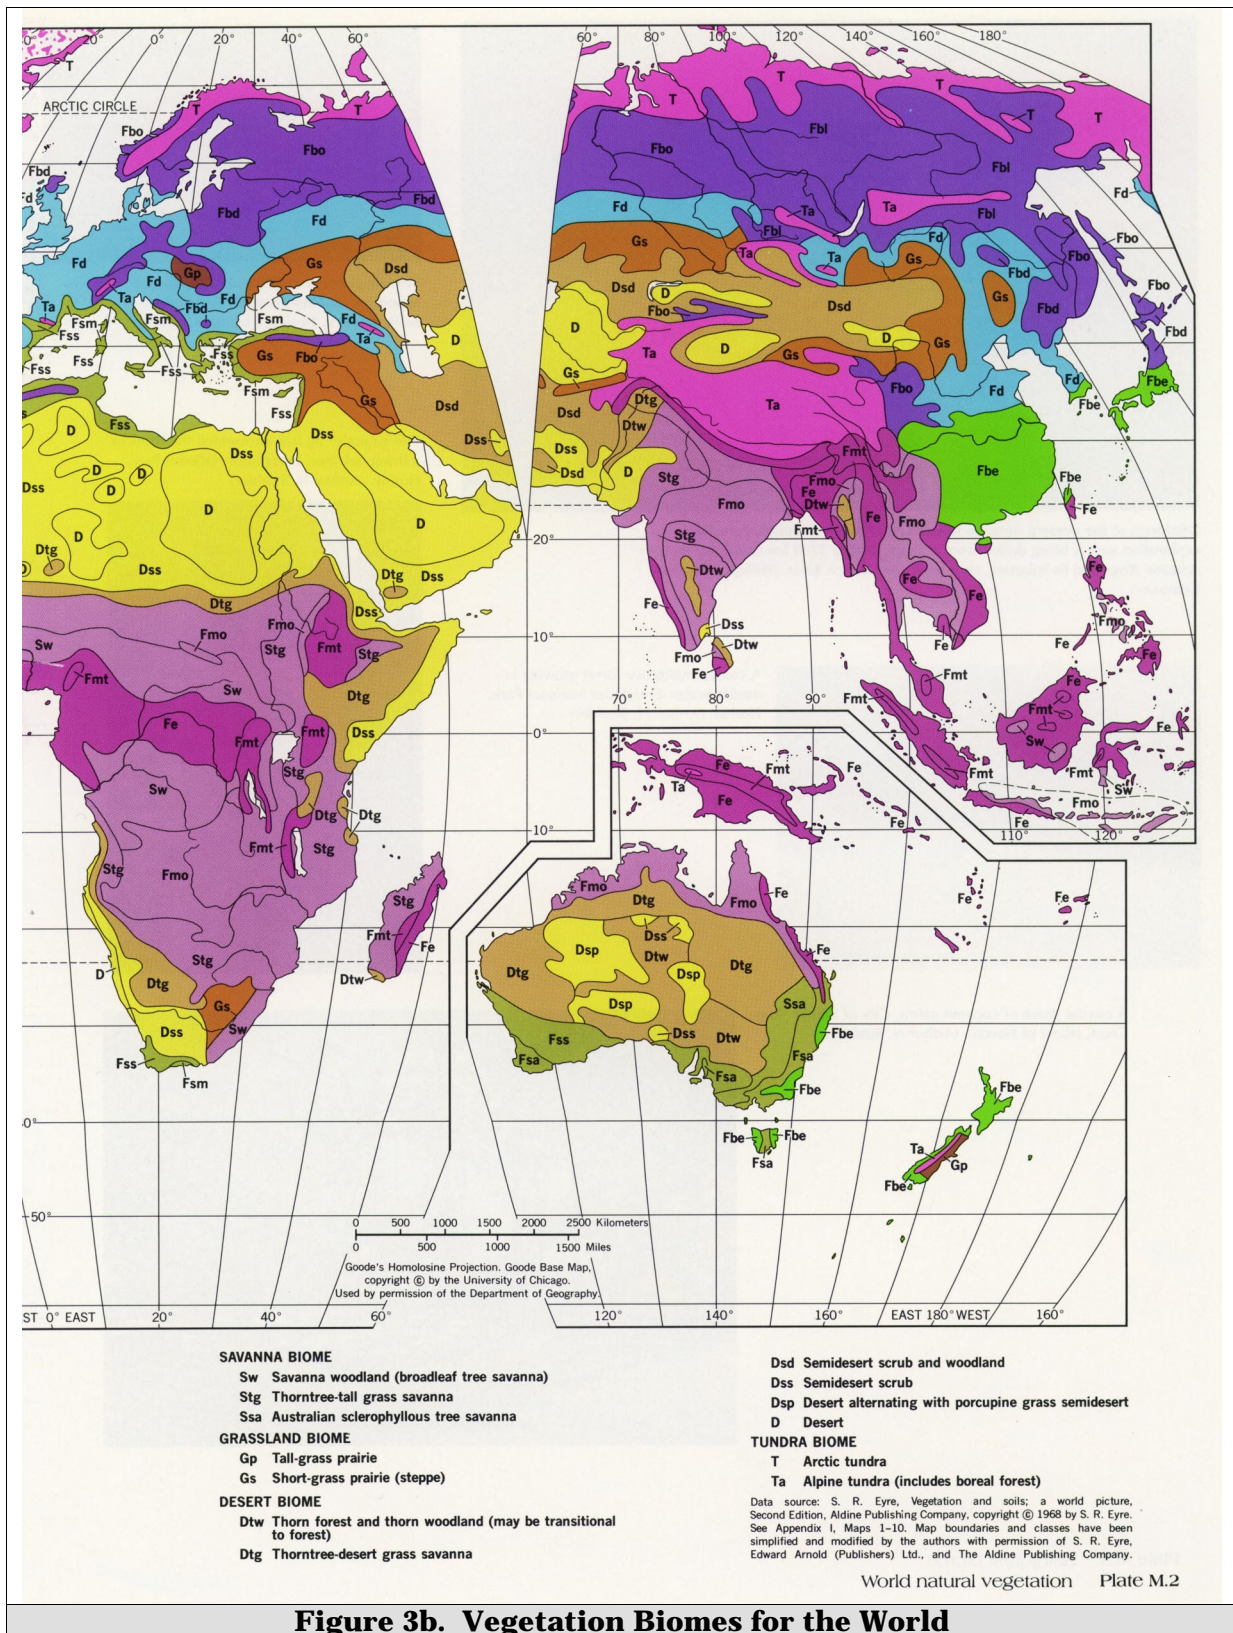

Figure 3b. Vegetation Biomes for the World

Fifteen geographic areas representing 13 sub-biomes were visited during the field data collection. Table 1 depicts the locations along with their sub-biome and climate definitions (if differentiated). Table 1 also offers a generalized or descriptive classification of the vegetation found in each of the sub-biome locations. Appendix B provides a detailed methodology about the selection of data collection locations (the general geographic area). It also provides detailed information about all of the data collection sites (the specific point on the ground from where data were collected) including data on canopy closure and undergrowth. Appendix C provides a general description of world climates with a link to each field collection location. Appendix D provides a description of the vegetation sub-biomes represented within the study.

Approximately two-thirds of the world's natural vegetation cover and all the major regional contingency (MRC) areas are represented in the regions selected for field collection. The remaining global sub-biomes were not evaluated because they fell into one of the following categories. First, several climates were void or nearly void of vegetation. These include several desert sub-biomes and several arctic sub-biomes. Second, small, unique areas located where the US Army is unlikely to deploy soldiers were excluded. These include the Great Lakes area and northern Siberia. Lastly, other sub-biomes that might be of future importance were eliminated due to prohibitive cost or restricted access.

The probable MRC locations were also used to select data collection locations. The Great Smoky Mountains National Park (referred to as Smoky Mountains throughout this report) and Willow Grove Naval Air Station (NAS) were selected because they are analogs to Korea. Natchaug State Forest (SF) and Fort Drum were selected because they are analogs to Bosnia. A detailed analysis describing how these analogs were selected can be found in appendix B.

Table 1. Vegetative Sub-Biome/Climate and Vegetation Definitions of Data Collection Locations		
Location	Sub-Biome/Climate Type	Vegetation Description
Panama - Gamboa	Monsoon Tropical/Tropical Wet-and-Dry	Monsoon (rainforest) - tropical deciduous forest
Panama - Fort Sherman	Tropical Rainforest/Tropic Wet	Monsoon (rainforest) - tropical deciduous forest
Panama - El Valle	Montane Forest/Tropic Upland	Equatorial and Tropical Rainforest - selva, broadleaf evergreen forest
Eglin Air Force Base (AFB), FL	Subtropical Broadleaf Evergreen Forest/Humid Subtropical	Oak and Pine Forest with some tropical vegetation
Fort Hood, TX	Dry Steppe (tall grass)	Tall Grass Prairie
Fort Carson, CO	Dry Steppe (short grass)	Short Grass Prairie
Fort Hunter-Liggett, CA	Sclerophyllus vegetation/Mediterranean	Old Oak Forest
Fort Lewis, WA	Coastal Forest/Temperate Oceanic (Marine)	Coastal Forest - largely needleleaf evergreen forest
Fort Benning, GA	Southern Pine Forest/Temperate (warm summer)	Southern Pine and Oak Forest
Great Smoky Mountains National Park, NC and TN	Midlatitude Deciduous Forest/Temperate (warm summer)	Mixed Deciduous Forest
Willow Grove Naval Air Station (NAS), PA	Midlatitude Deciduous Forest/Temperate (warm summer)	Mixed Deciduous Forest
Natchaug State Forest (SF), CT	Midlatitude Deciduous Forest/Temperate (cool summer)	Mixed Deciduous Forest
Fort Drum, NY	Mixed Boreal and Deciduous Forest/Temperate (cool summer)	Mixed Deciduous and Pine Forest
Canada - Gagetown Training Area (New Brunswick)	Mixed Boreal and Deciduous Forest/Temperate (cool summer)	Mixed Deciduous and Pine Forest
Fort Greely, AK	Boreal and Taiga	Mixed Spruce, Birch and Aspen

Site Selection

Once a primary geographic location within a sub-biome was selected, a data collection team visited the location. Typically, this visit consisted of 1 day of reconnaissance and 4 days of data collection. The reconnaissance was used to select potential sites for data collection. The field team assessed the potential sites and selected several (usually four) sites best representing the geographic area using the following three criteria for site selection. First, because disturbed vegetation would result in unrealistic LOS curves, the data collection team looked for areas with a minimum of damage due to traffic or natural disaster. Second, consistent with the third assumption of the study, only gently sloping and flat areas were considered for data collection. While it was not always possible to eliminate elevation changes in the site selection process, it was essential to find areas as level as possible in order to examine only the effects of vegetation. Lastly, the data collection team looked for vegetation typical of the locations in order to collect data representing a good cross section of the geographic area. After data collection and subsequent analysis of the four representative sites, the parameters of a "best" or recommended site were selected for model input.

Tactical Considerations for Data Collection

Once sites were selected for data collection, a location on the ground representing a tactical defensive position for a dismounted soldier was identified. The sites were selected based on terrain, tactics, mission, and enemy. The exact position within a vegetated area was selected by a career infantryman (noncommissioned officer) to represent a sound tactical position for a prone soldier.

A tactical field of view (FOV) was selected for data collection so the data would represent a potential real-world situation. Data were collected along azimuths (measured from grid north) within the tactical FOV. In every location visited, there were situations where the vegetation (either the undergrowth or a tree trunk) would block LOS at close range. At the other extreme, there were phenomena nicknamed "keyholes." These keyholes allowed visibility at long ranges where surrounding LOS was much shorter. For example, at one Fort Lewis location, the LOS along most azimuths was less than 50 meters. However, along one azimuth the LOS was over 90 meters. Rather than biasing the data collection by selecting or not selecting these extreme conditions, a stratified sampling technique was used. Magnetic north was determined (using a military compass) and then the offset to grid north was found using map information. A uniform spacing between azimuths, usually 10 degrees, was selected. This procedure allowed for the potential inclusion of these extreme conditions but data analysis treated them as outliers.

Data Collection Methodology

Introduction. The data collection methodology can be separated into four sections: the points of view from which data were collected, how the target silhouette was

designed for data collection, how the tactical field of view and azimuths were determined, and why humans were used to collect data.

Data Collection Points of View. Data were collected from both the defender and the attacker points of view. From both points of view, data were collected for both a prone (0.25 meter above the ground) and a crouching (1.5 meters above the ground) observer posture. For each posture (prone and crouching), data were collected to determine how much of the kneeling target was visible. The kneeling target was divided in such a manner that the visible portion of the prone target could also be calculated from the kneeling target (discussed next). This resulted in eight different defender/attacker viewpoint combinations.

The Target

The kneeling target silhouette (see figure 4) was 1.015 meters tall and divided into three nearly rectangular sections representing the head, torso (neck to waist), and the legs (waist to knees). The three sections of the silhouettes were painted with different ordered combinations of the three colors (e.g., pink head, orange torso, and yellow legs) and the silhouette with the highest contrast was selected for use. The torso and the legs were separated so the bottom section represented the height of a prone soldier. This allowed for data to be collected for a kneeling and prone soldier simultaneously. The rectangular areas made it easier for the data collection team to estimate the percentage of an area not obscured by vegetation.

cm - centimeter

mm - millimeter

The local vegetation, sun angle, and the preference of the data collectors determined the silhouette used along each azimuth. The target silhouette was placed on the ground, facing the data collectors, at several locations along the azimuth. The silhouette was placed on the ground at locations where changes in vegetation affected LOS. For example, if a tree was in line with an azimuth, the target was placed in front of the tree and behind the tree. This allowed for the exact point where major changes in LOS were to be recorded. Figure 5 shows a sample azimuth and the location where the target would be placed.

A data collection problem occurred when vegetation was the same color as the target silhouette and, therefore, difficult to discriminate between the silhouette and the surrounding vegetation. This problem was overcome by moving the target up and down and relying on the observer to determine what was the target and what was vegetation.

Tactical Fields of View and Azimuth Selection

Data were collected at each site in the tactical field of view by moving the kneeling target silhouette away from the defensive position along several azimuths. Usually, these azimuths were 10 degrees apart. The percent of target visible at different distances was recorded. The silhouette was moved away from the defensive position until either the terrain began to interfere with the collection process (this rarely happened) or until the target was totally concealed by vegetation. A total survey station (TSS) was used to keep the target precisely on line to determine the exact distance between the defender location and the silhouette.

Survey flags were used to locate every point along each azimuth where data were collected. After the data were collected from the defender position, the silhouette was placed at the defender location and data were collected from the attacker point of view.

Human Data Collectors

Most of the data collected for this study were obtained using the unaided human eye. However, when ranges exceeded about 100 meters, the data collectors had the option to use binoculars. An example of a data sheet can be seen in figure 6.

Several methods were explored to analytically determine the percent of the target silhouette seen through vegetation. These included digital cameras, infrared photography, standard photography with telephoto lens, and human data collectors.

Two problems with digital cameras could not be overcome. First, currently available digital cameras did not produce enough resolution. In particular, at 140 meters, the target silhouette was 3 pixels wide and 5 pixels high. This number of pixels restricted the amount of target observed to a small range of values limiting meaningful analysis. Secondly, the digital camera blended colors. For example, if the target was orange and the background vegetation was green, pixels along the edge of the target would appear as different shades of brown. A digital camera could not separate colors on the target from the colors existing in the collection area, regardless of how brightly the target was painted or how much the target colors contrasted with the surrounding vegetation of any collection site.

Infrared (IR) photography was eliminated primarily because of cost and lack of a subject matter expert in IR photography. A means to produce a mobile, hand-held target silhouette, which could be heated in a field environment would have been time consuming, costly, and have unknown reliability. Another unknown was the cost of the IR film and its processing. The field collection effort was expensive and the data collectors needed to be sure all of the data were complete before leaving the area. If there was a problem with the film processing, all data would have been lost. Yet another problem with IR photography was the effects of the solar radiation on the vegetation. It was not known how the heat produced in vegetation from absorbing sunlight for several hours and the heat of the person holding the target could be separated from the artificially heated target silhouette.

Standard photography with a telephoto lens was also evaluated as a data collection technique. First, there was a problem with the enormous number of photographs required. The target was placed on the ground and evaluated over 5,000 times during this study. This would have required 5,000 photographs and each photograph would have had to be electronically scanned and analyzed. During the development of the data collection methodology, a second problem was discovered. Although the silhouette was brightly painted, contrasting colors assumed to exist only on the silhouette, were found in nature. These similar colors would have been counted as "visible" during the evaluation phase of these photographs.

Figure 6. Sample Data Collection Sheet

It was eventually decided the best readily available optical device was the human eye. Although the human eye is among the most discriminating sensors, it is the brain producing the images we perceive. The brain has a lifetime of biases built into it as evidenced by the fact that different people "see" things different ways.

A methodology was developed to measure and minimize other sources of observer bias and is discussed next.

Before the field collection began, all participants were tested to measure bias and accuracy of the estimations they would have to make. A test consisting of random black and white patterns was presented to the data collectors and they estimated the percentage of the pattern that was black. The average deviation between each observer's estimate and the actual values was between 5.4 and 9.7 percentage points. None of the data collectors were biased towards over-estimating or under-estimating the percentages. They were then retested with one additional set of information. Random patterns containing exactly 10, 20, 25, 30, 33.33, 40, and 50 percent black coverage were produced. The data collectors were asked to compare the unknown patterns to the known patterns. This reduced the average errors to between 2.7 and 5.7 percentage points. These random pattern plots were available to the field personnel during the collection process. A further analysis of the test results indicated these errors could be reduced to between 1.7 and 4.8 percentage points by using a second observer. Additional observers would have increased the accuracy of the estimates, but this improvement in accuracy would not justify the increased resources required.

Analysis

Introduction

The analysis begins by examining a sample of the raw data, and identifying the three functions to be used in attempting a curve fit of that data. As data were collected at more than 60 sites, the method of selecting the most representative site is discussed next. This is followed by a description of the method of selecting the best parameters for each of the selected functions. Ancillary to this, the correlations between the decay parameter of the exponential functions and various descriptors of the undergrowth are presented. Some comments on unexpected results in the Panama data, and insights of the data collection observers, conclude the analysis.

Appendix E provides a complete record of the raw data, further explanation of the three curve fits, and coefficients for the curve fits for each of the collection sites.

Raw Data

Figure 7 provides a sample of the raw data collected along each azimuth, the quartiles (the middle 50 percent of the data), and the median of the data. The analysis focuses on the median curve because it represents the most realistic representation of visibility in the field. The mean of the data was not used because outliers could skew the entire curve. Data were collected to represent looking at a kneeling target and a prone target. The kneeling target was 0.4206 square meter and the prone target was 0.12325 square meter. The y-axis of these plots is based on whether the target viewed was kneeling or prone. For example, if 100 percent of a kneeling target was seen, 0.4206 square meter was visible and if 100 percent of the prone target was seen, 0.12325 square meter was visible. The presented size of the target (number of square meters visible) is used in the detection equations.

The defensive positions selected for the field survey were selected as typical prone defensive positions. Data were collected between a crouching defender and a prone and kneeling attacker for comparison purposes only. This data is provided in the appendix but is not discussed in the analysis.

Curve Fits

The fits to three different curves were selected in this analysis to provide different approaches to represent the effects of vegetation on LOS. The three functions fitted to the raw data are an exponential decay curve, a field exponential decay curve, and a pole-zero fit.

The exponential function takes the form:

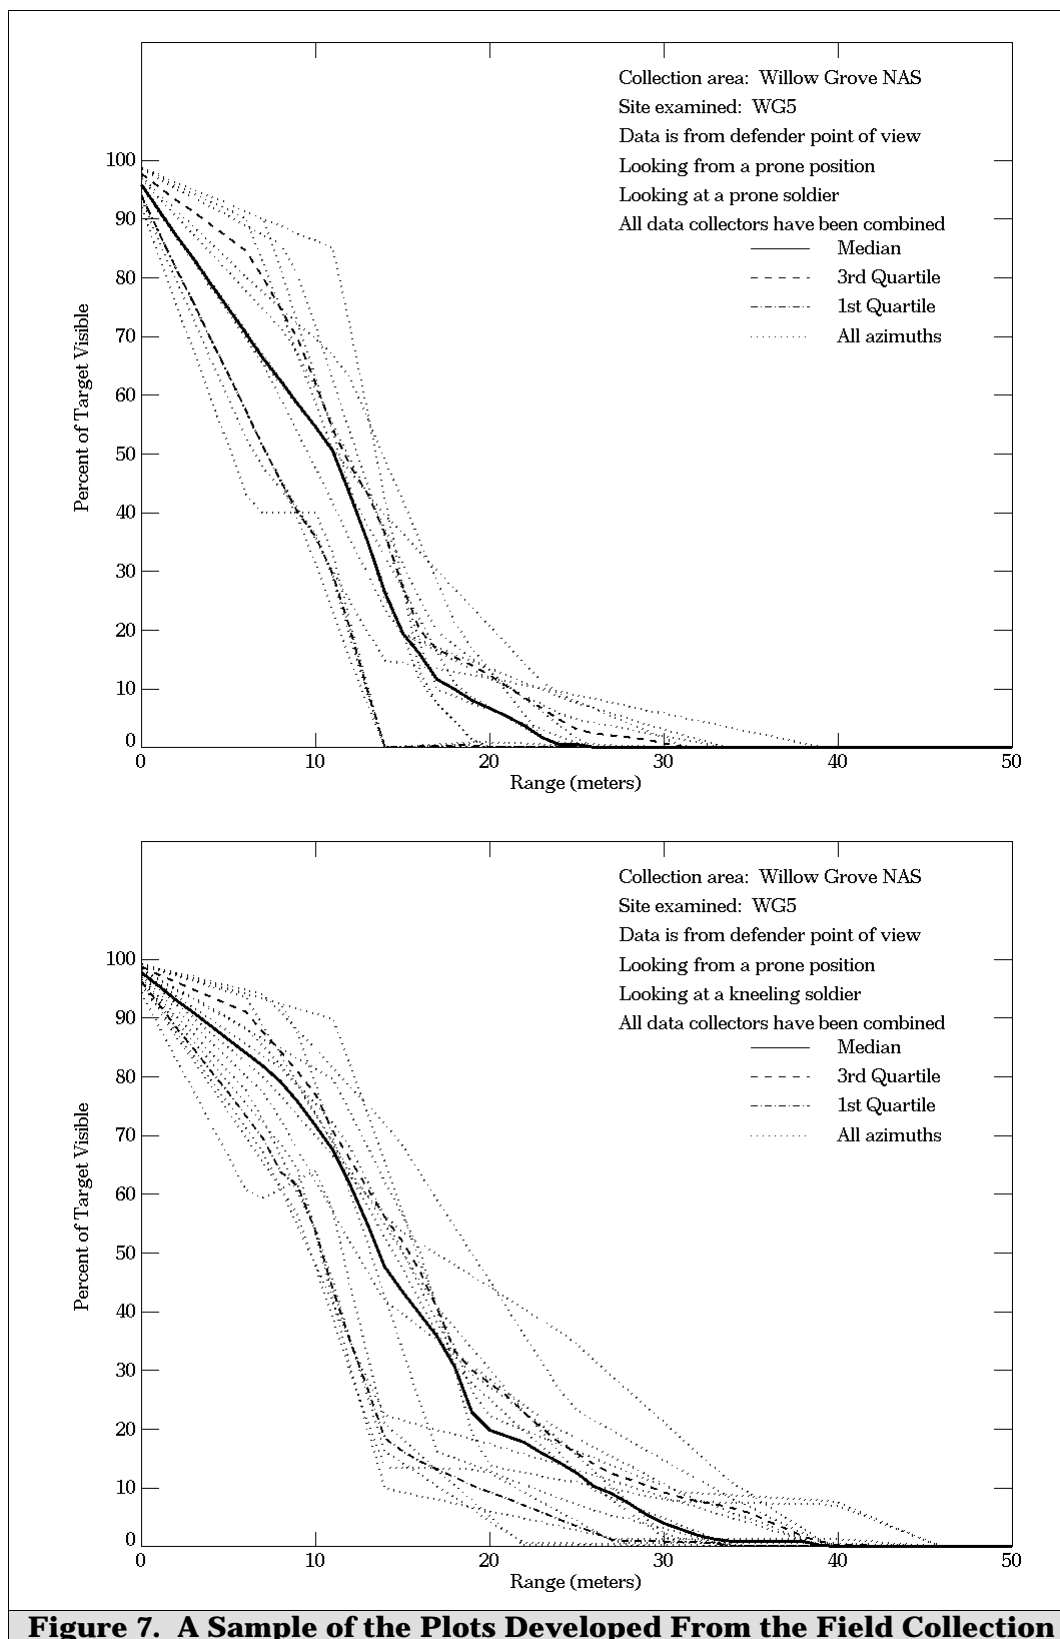

$$f = e^{-\frac{R}{b}},$$

where **f** is the visible fraction of the target, **R** is the range of LOS, and **b** represents the slope of the decay. A smaller value for **b** implies a steeper decay curve.

The field exponential equation takes the form:

$$f = e^{-\frac{R-a}{b}},$$

where **a** represents the range at which the curve begins the decay. The value of **a** delays the decay until a certain range is exceeded. This second parameter in the exponential decay allows more flexibility in fitting the data.

The pole-zero was included in the analysis because it was usually the best fit of the three curves. This equation is a version of the frequency response equation from electronic circuit analysis. It takes on the form:

$$\mathbf{f} = \alpha \left[\frac{\delta^\gamma + \mathbf{R}^\gamma}{\varepsilon^\gamma + \mathbf{R}^\gamma} \right],$$

where α is a scaling factor and δ represent the part of the curve where the decay is so gradual that it is insignificant. The ε parameter represents the range where the curve begins to turn downward. In other words, this is the distance where the target begins a significant degradation. The γ parameter, the exponent in the equation, is a measure of how quickly the signal degrades as range becomes larger than ε .

Representative Data Sites

Data were collected at several (between one and six) sites at each location. The parameters to all three curve fits and for each site are provided in appendix E. The sites at each location were analyzed and a site representative of a biome was selected by examining three different factors. First, the undergrowth data collected at each location was examined. The sites were subjectively ranked based on the most representative undergrowth type, median undergrowth height, and maximum undergrowth height. Second, the raw data curves, along with the field notes, were examined and the sites were subjectively ranked based on how well the site represented the location. Some of the sites were eliminated by this analysis because they were classified as outliers. Lastly, the data parameters for all three curves were examined and ranked based on the sum of squares (a measure of error between the raw and the fitted data). The best representative site at each location (table 2) was selected on the basis of these three approaches.

Table 2. Best Representative Sites for Each Location

Parameter Selection

Tables 3 through 6 depict the exponential fits for four combinations of point of view, attacker posture, and defender posture. Tables 7 through 10 depict the field exponential fits and tables 11 through 14 depict the data fits for the pole-zero fits.

The sum of square error (SSE) for each fit is provided in the tables as a measure of error in the curve fit. Typically, as expected, the more parameters in a function, the smaller the SSE (and the better the fit). In every case, the field exponential fits (with two parameters) have smaller SSE than the exponential fits (with one parameter). The pole-zero fits (with four parameters) have a smaller SSE than all of the exponential fits and for about three-quarters of the field exponential fits. When the pole-zero SSE was higher than the field exponential SSE, the differences are either very close (i.e., 0.107 versus 0.113) or both of the SSEs were very small (i.e., 0.022 versus 0.038).

The **b** parameters in tables 3 through 6 describes how quickly the exponential curve decays. A small value (i.e., Panama and Eglin AFB) reflect a rapid decay and a larger value (i.e., Fort Carson and Fort Hunter-Liggett) depict a more gradual decay. The **a** and **b** parameters in tables 7 through 10 depict the beginning of the decay and the slope of the decay. For example, the fitted curve for Eglin AFB (from table 9) begins decaying at 1.598 meters and a decay factor of 3.73 indicates that the decay occurs very quickly. On the other hand, the decay for the Fort Hunter-Liggett curve fit begins at 15.427 meters and the decay factor of 16.385 indicates that the decay occurs very slowly.

Five of the sites from table 2 have been selected to depict how the different parameters are reflected in the graphs. Parameters for a prone defender looking at a kneeling attacker for Panama (gam2), Fort Greely (G02), Fort Drum (7G), Fort Carson (car28), and Fort Hunter-Liggett (hl10) were selected to provide a variety of biomes and to span the different values of the coefficients. Figures 8 through 11 depict the field measured data, the exponential fits, the field exponential fits, and the pole-zero fits, respectively. Data from tables 4, 8, and 12 were used to generate these figures.

Relationship of the Undergrowth to the LOS Parameters

It was expected that as a target moved farther from the observer, the target would eventually disappear behind a wall of trees. This was rarely the case. The major inhibitor of visibility for most places was the undergrowth, not the trees. Only three types of data were collected to measure the undergrowth of the collection sites. This data included a general description of the undergrowth (very sparse to very dense), the mean height of the undergrowth, and the maximum height of the undergrowth. This data is presented in table B-5, appendix B. The correlation between the exponential decay parameter and each of the undergrowth factors (along with five other factors: annual rainfall, percent evergreen trees, elevation, percent canopy closure, and latitude) is included in table 15. An analysis of the data identified the Boreal and Mediterranean biomes as outliers. When these outliers were removed from the analysis, the correlation improved for the undergrowth density with the exponential decay parameter from -0.44 to -0.70.

Table 15. Correlation of Collected Data and Exponential Parameters for the Prone Defender Looking at the Kneeling Attacker

Factors	Correlation
Undergrowth Density	-0.44
Annual Rainfall	-0.39
Maximum Undergrowth Height	-0.34
Mean Undergrowth Height	-0.24
Percent Evergreen Trees	-0.24
Elevation	0.22
Percent Canopy Closure	-0.16
Latitude	-0.03

The subjective descriptions of undergrowth were given ordinal values between 1 and 7. The corresponding descriptions are:

- 1 - very sparse
- 2 - sparse
- 3 - sparse to medium
- 4 - medium
- 5 - medium to dense
- 6 - dense
- 7 - very dense

The three undergrowth parameters provide some of the stronger correlations, but they are the most subjective data in the table. The undergrowth patterns in Panama presented another problem. The data collection locations in Panama had few mature trees and the undergrowth was indistinguishable from the trees. It is possible that a more objective approach to collecting undergrowth information would provide a larger (absolute value) correlation. A better approach to collecting undergrowth data for the above table could be using regression equations that accurately predict the decay parameters which would, in turn, provide more realistic visibility in vegetation.

Panama Discussion

Data were collected in Panama twice. The first data collection coincided with the end of the worst drought in over 100 years. Because the vegetation appeared dry and sparse during the first data collection, data were collected a second time at the end of Panama's rainy season. Surprisingly, the visibility during the two trips was virtually equal. The differences in the fitted curves for the El Valle site for the two trips are less than one percent across all ranges. The vegetation parameters for the sites at Gamboa and Fort Sherman indicate that the vegetation was slightly denser the second trip. However, the difference was undistinguishable by the data collection team and was apparent only after the data were analyzed and plotted. The analysis showed that for the two visits, the difference between corresponding best fit curves, for any given range, was always less than 5 percent.

Data Collection Observations

As the study progressed, the data collection team developed insights as to how vegetation obscures visibility. These insights were gained post priori and are not included in the analysis section. Since the authors consider them important factors concerning how vegetation obscures visibility, they are discussed in the paragraphs below, and should be addressed in future data collection.

A priori, it was expected that the portion of the target silhouette visible would decrease steadily as a function of range; this was generally reflected in the data. For example, the medium value for the LOS had a downward trend. All of the curve fits presented a steady decrease in target visibility as range increased.

However, for one-third of the azimuths, the fraction of the target that was visible increased at longer ranges. But, when the median was calculated for the site, the data generally had a downward trend. All of the curve fits presented a steady decrease in target visible as range increased. There are two reasons why the portion of the target visible increased at longer ranges. First, the undergrowth blocking part of the target at close range does not block the target as much at longer ranges. For example, consider a bush obscuring the bottom part of the target at close range. Assuming no other obstructing features, the sensor looks over the bush and can see more of the target as the target is moved away along the azimuth line.

The second reason is a consequence of the discrepancy between the assumptions of the LOS problem and the sensors used in the experiments. When an observer uses both his eyes (aided and unaided) to observe, he is in conflict with the mathematical description of the problem. The image perceived by the observer is the brain's fusion of the scene presented by **each** of the observer's eyes, and depending on the geometry of the situation, some of the obscuration may be eliminated. The mathematical description of the problem assumes that the observer is a single point perceiving a single image. One can demonstrate this effect by holding a thumb in front of himself, and observing the scene one eye at a time, and then with both eyes. Clearly the obscured portion of the scene is different in all three cases.

A second insight into visibility in vegetation concerns how the different postures of the observers, whether prone or crouching, changed the view of the target. The fitted curve parameters all indicate that crouching soldiers have better visibility than prone soldiers. However, occasionally the undergrowth and crowns of trees blocking the view of the crouching soldier did not block the view of the prone soldier.

The final insight came from one of the infantry subject matter experts. Based on the collected field data, it was noticed that, in general, visibility from the point of view of the attacker declines faster than the visibility of the corresponding defender. This was especially true when they were both in their typical posture (prone defender, kneeling attacker). Therefore, a range exists where the defender has a significant advantage over the attacker. Further analysis of this aspect of visibility could lead to changes in dismounted infantry tactics by providing soldiers with a set of engagement ranges as a function of biome giving them the advantage over the attacker.

Conclusions

This study shows that LOS in vegetation can be accurately portrayed. Therefore, simulations representing LOS in vegetation should reflect the information in this report. Three equations have been developed allowing for the modification of LOS algorithms in combat models. These equations can be used to verify the vegetation density portrayed in simulators/simulations by comparing LOS in the simulators to the curves presented in this report.

Recommendations

This study examined the environment where trees were in full foliage. A follow-on study should be conducted examining the effects of trees without leaves.

The undergrowth played a very important part in blocking visibility. A more detailed analysis of the effects of undergrowth should be conducted.

Since the analysis required to select analog sites for the former Yugoslavia and Korea was not field checked outside the continental US (OCONUS), it is recommended that data actually be collected at these OCONUS sites.

Now that the analysis on dismounted infantry targets is complete, this work should be expanded to examine the effects of LOS on vehicle sized targets.

Appendix A. Probability of Detection (PDET)

Introduction

This appendix describes the empirical model, Acquire, used to determine probability of detection (PDET) for combat simulations. This model was developed by Night Vision Electronic Sensor Division based on extensive field tests. These tests were designed for long ranges (up to 10 kilometers) and for the use of forward looking infrared (FLIR) sights. These equations, however, have been extrapolated for direct view optics (DVO).

For the purpose of this study, the application of the Acquire model to determine PDET is only examined for sensors using DVO and dismounted infantry targets. DVO, for the purposes of this discussion, represents the unaided eye or binoculars.

Appendix A first describes the physics equations determining PDET. In order to visualize how the physics model works, a discussion of the inputs used by the Combined Arms and Support Task Force Evaluation Model (CASTFOREM) in a recent dismounted infantry study are also included.

Description of the Models

The models used to determine PDET can be separated into the following steps:

- Contrast (C)
- Apparent contrast (AC)
- Maximum resolvable frequency (MRF)
- Resolvable cycles (N)
- Target transfer probability function (TTPF)

Contrast (C)

Contrast (also called inherent contrast) is defined as the absolute value of the ratio of background brightness and target brightness. The equation is as follows:

$$C = \left| \frac{BB - TB}{BB} \right|,$$

where BB = background brightness

TB = target brightness

Apparent Contrast (AC)

The apparent contrast of a target requires several input parameters. This equation models the effects of the atmosphere on the transmission of contrast. The resulting equation is as follows:

$$AC = \frac{C}{1 + SOG \left(e^{ATTN * Range(Km)} - 1 \right)},$$

where SOG = sky over ground ratio

ATTN = atmospheric attenuation

Range (km) = Range to target in kilometers

SOG is defined as the ratio of sky over ground luminance. It is a function of ground reflectance, cloud cover, and solar geometry. A SOG of 1.0 is used for a night scenario. ATTN is defined as the atmospheric extinction coefficient.

Maximum Resolvable Frequency (MRF)

The MRF (also called the spatial frequency) is a lookup table considering the visible light and the AC. Nine light levels varying from a star-lit night to clear day are used by CASTFOREM.

AC values not found in the table are computed by a linear interpolation between values in the table. The MRF is then multiplied by the power of the optics used. The MRF is multiplied by 1.0 for an unaided eye and by 7.0 for seven power binoculars.

Resolvable Cycles (N)

Resolvable cycles (N) is defined as the number of black and white bars distinguishable in a target. It is a measure of the ability of the optic device in use to determine detail. As the value of N increases, targets become more distinguishable because the observer can see more detail. The resolvable cycles is computed as follows:

$$N = \frac{MRF \cdot CD}{Range(km)},$$

where CD = square root of the presented target area

Range (km) = distance to the target in kilometers

Target Transfer Probability Function (TTPF)

The TTPF is also the probability of detection given an infinite amount of time. It is defined as follows:

$$\mathbf{PDET} = \frac{\left(\frac{N}{N50}\right)^E}{1 + \left(\frac{N}{N50}\right)^E},$$

where $E = 2.7 + 0.7 \cdot N/N50$

$N50$ = Resolvable cycles required to acquire at a specific acquisition

An $N50$ value of 0.75 is used to represent a man moving and standing and a value of 1.00 is used to represent a man kneeling and stationary. The existence of detection in CASTFOREM is determined by comparing PDET to a random number between zero and one.

Example

A typical European scenario in CASTFOREM is examined to illustrate how the inputs actually effect PDET. Since every target pairing in every simulation will have different input parameters, these numbers should only be viewed as an example and should not be used in combat simulations.

Contrast was defined as 0.36 for dismounted soldiers in a recent dismounted infantry scenario. This value approximates the contrast of a man in fatigues surrounded by growing deciduous trees. Different targets in different environments will yield different contrast values.

SOG is defined as 2.6 for a European type environment. In comparison, a SOG of 1.47 is used in Southwest Asia. An attenuation of 0.3566 was used for Europe.

Ranges up to 400 meters were used for this example because the field collection never encountered a visible target beyond 400 meters. Table A-1 gives the values of AC as a function of range.

Table A-1. Values of Apparent Contrast as a Function of Range in a European Scenario	
Range (Meters)	AC
1	0.36
25	0.35
50	0.34
100	0.33
200	0.30
400	0.27

A close examination of the AC equation shows the maximum value for AC is C (0.36 in this case). The MRF table for AC values between 0.25 and 0.36 (the approximate values of AC between 0 and 400 meters) is in table A-2. Included in the table is the range for which the value of AC is associated. MRF is a function of AC and is not a function of range. Range was added to this table because it is easier to understand than contrast.

Table A-2. Minimum Resolvable Frequency for Different Light Levels and Different Values of AC

AC	Associated Range (m)	Light Level Code*								
		9	8	7	6	5	4	3	2	1
0.25	438	1.579	1.520	1.353	1.094	0.745	0.285	0.031	0.014	0.002
0.30	208	1.657	1.598	1.427	1.160	0.799	0.325	0.044	0.021	0.003
0.35	30	1.726	1.660	1.492	1.218	0.847	0.358	0.057	0.029	0.005
0.36**	0	1.787	1.726	1.550	1.270	0.889	0.389	0.071	0.037	0.008

*The light level codes are as follows: 1 - Clear - No Moon/Starlight, 2 - Starlight/Quarter Moon, 3 - Moonlight/Full Moon, 4 - Just After Twilight, 5 - Just Before Twilight, 6 - Sunset, 7 - Heavily Overcast Day, 8 - Overcast Day, 9 - Clear Day.

** The MRF values for 0.36 were interpolated from the actual CASTFOREM inputs.

m - meters

Five of the nine light levels were examined: clear day, just before twilight, just after twilight, moonlight/full moon, and clear - no moon/starlight. Two sizes of moving targets are depicted in this example. The target sizes were for a fully exposed kneeling soldier (0.4206 square meter), and a fully exposed prone soldier (0.1233 square meter). However, the actual presented area of a soldier typically decreases as a function of range (in a vegetated environment) and vegetation density.

Table A-3 contains the MRF values for five light conditions. Table A-4 and table A-5 contain the values of N for different light conditions for a fully exposed kneeling and prone soldier, respectively. Figure A-1 and figure A-2 depict the PDET for different lighting conditions for a fully exposed kneeling and prone soldier, respectively. Values for AC have been replaced by range to make the example more straightforward. The actual equations require the AC values.

Table A-3. MRF Values for Five Light Conditions

Range (m)	Light Conditions				
	Clear Day	Just Before Twilight	Just After Twilight	Moonlight/ Full Moon	Clear - No Moon/ Starlight
1	1.787	0.889	0.389	0.071	0.008
25	1.736	0.854	0.363	0.059	0.006
50	1.718	0.839	0.354	0.056	0.005
100	1.695	0.825	0.345	0.052	0.004
200	1.654	0.801	0.324	0.044	0.003
400	1.592	0.754	0.292	0.033	0.002

Table A-4. Value of N for Different Light Conditions - Fully Exposed Kneeling Target on the Move

Range (m)	Light Conditions				
	Clear Day	Just Before Twilight	Just After Twilight	Moonlight/ Full Moon	Clear - No Moon/ Starlight
1	1158.935	576.549	252.281	46.046	5.188
25	45.034	22.154	9.417	1.531	0.156

Appendix B. Description of Data Collection Locations and Sites

Introduction

Fifteen geographic areas were selected for data collection. They represent a variety of vegetative sub-biomes, climates, latitudes, elevations, and therefore a variety of vegetation densities. This appendix provides a detailed description of the locations (general geographic area) and sites (specific point on the ground) where data were collected. It includes a discussion on how the sites were selected and detailed information about each location and site.

A compact disk-read only memory (CD-ROM) is included with this report. This CD-ROM provides two types of graphical information. Maps are included to represent the data collection locations. The actual sites selected for data collection are indicated by pink or red dots. Vegetation panoramas are included. Each of the data collection sites was photographed and provided.

Selection of Geographic Locations for Data Collection

Based on the initial scope and funding levels for the study, the TEC and TRAC-WSMR scientists decided to limit the field LOS investigations to the CONUS sites. The criteria used to select the study areas of interest were: (1) the probable locations of the US Army's future MRC, (2) world vegetative biome information, and (3) locations where field collections could be conducted.

All of the potential MRCs are located OCONUS and are often in unfriendly countries. The locations are Central America, the former Yugoslavia, and Korea. It was decided that areas with similar vegetation characteristics (based on vegetation, climate, elevation, and latitude) should be included in selecting collection locations. A climatologist from TEC developed a set of criteria enabling the field collectors to select CONUS areas best representing the former Yugoslavia and Korea. A detailed description of this methodology is described later in this section (see "Former Yugoslavia and Korea Analog Analysis").

While climates are better understood than biomes, biomes categorize vegetation types better than climate categories. A map (see figure B-1) depicting global vegetative biomes was consulted to identify US/world analogs (The CD-ROM included in this report depicts this picture in high resolution color.). The major vegetative biomes are delineated primarily on the basis of their specific vegetation types, i.e., forest, savanna, grassland, desert, and tundra. Each biome is further divided into smaller vegetation units or "sub-biomes" associated with vegetation structure, climate, soil types, soil moisture, and predominant species. In order to assure the best possible representation between CONUS locations and the rest of the world, the field collection sites for this study were selected from the sub-biome units identified in figure B-1. Eight CONUS sites were identified. Each site was situated in a corresponding sub-biome as follows:

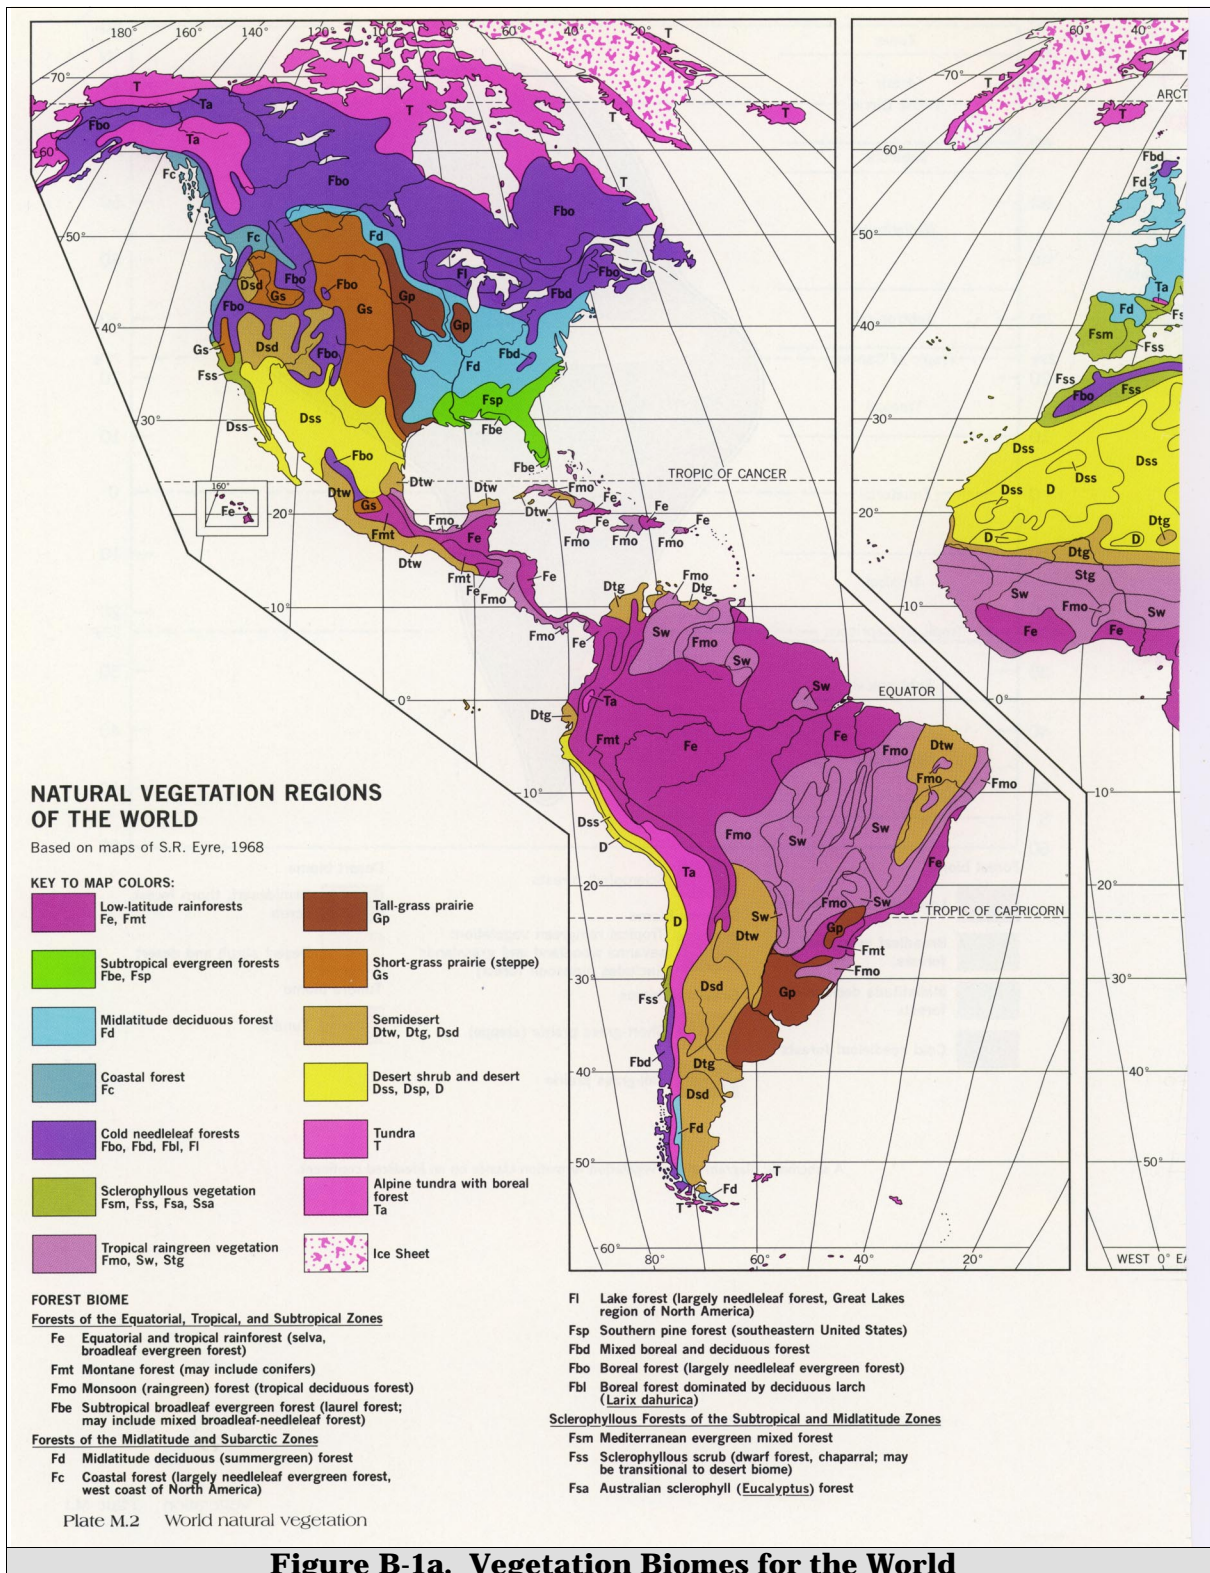

Figure B-1a. Vegetation Biomes for the World

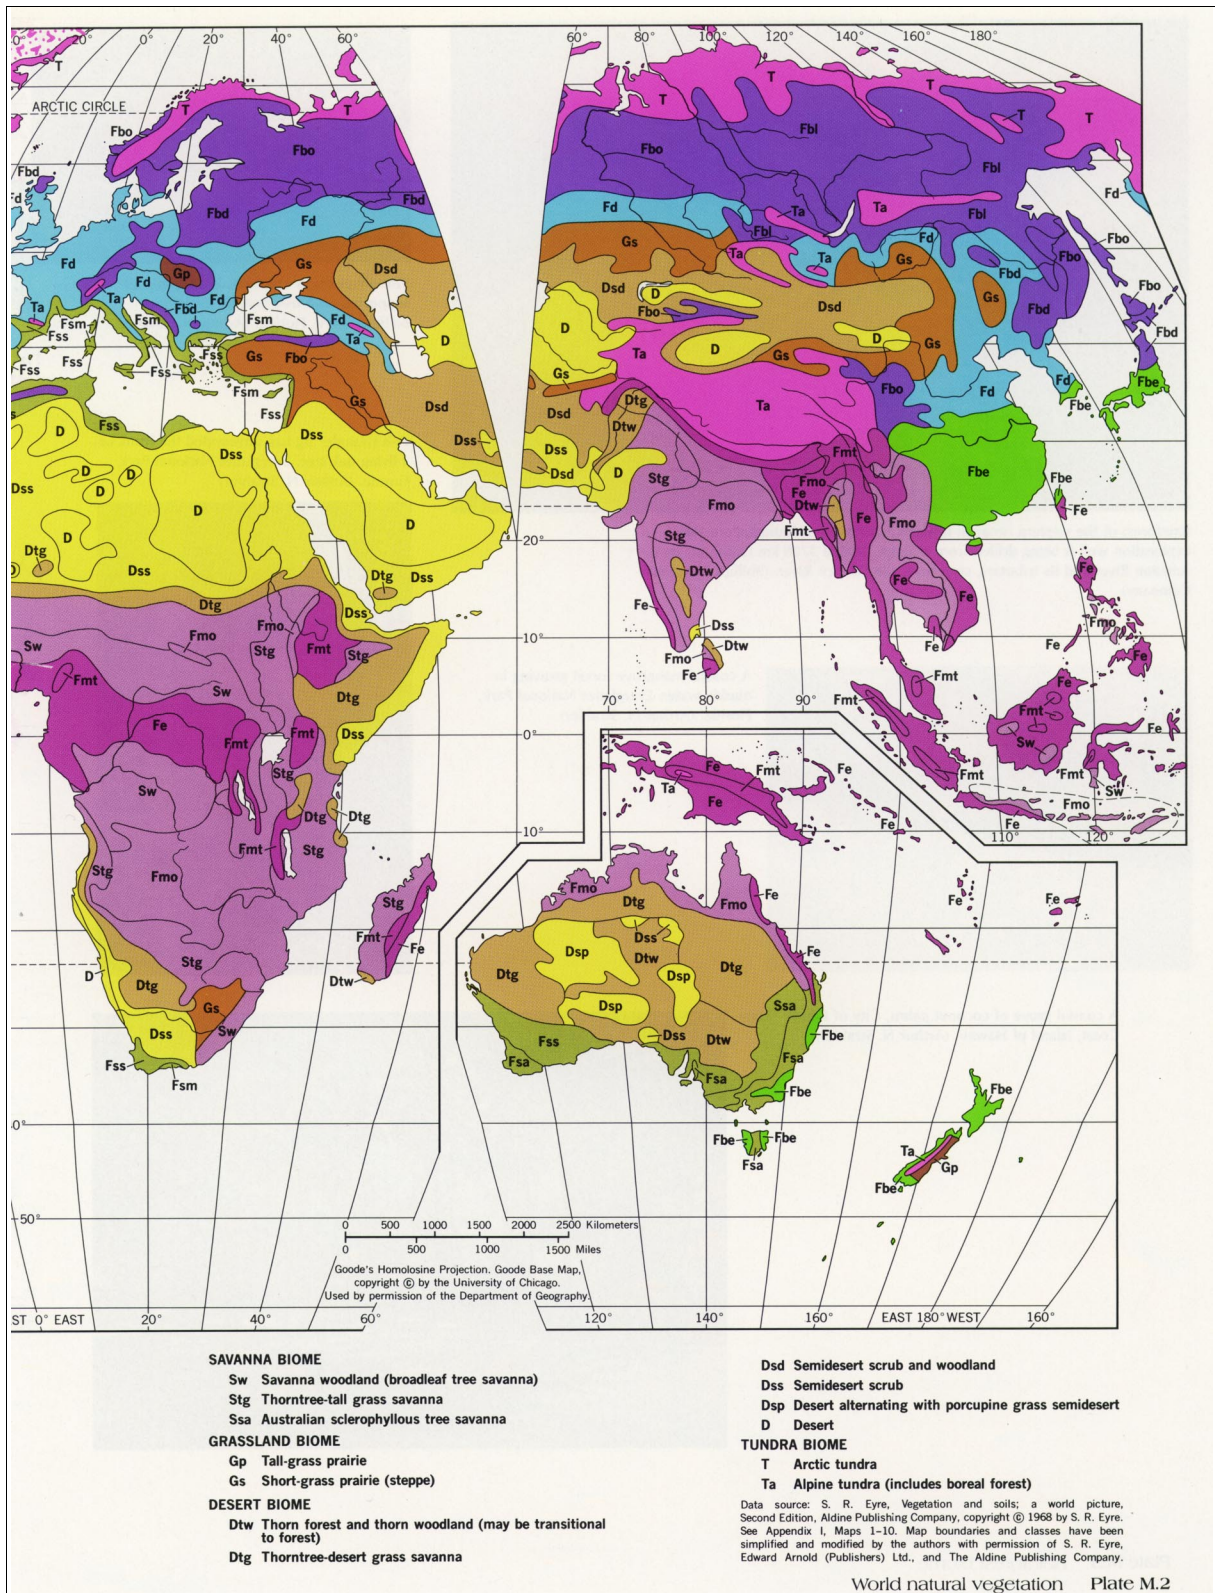

Figure B-1b. Vegetation Biomes for the World

- Coastal Forest (Marine West Coast)
- Sclerophyllous Vegetation (Mediterranean)
- Short Grass Prairie (Steppe)
- Tall Grass Prairie
- Mixed Boreal and Deciduous
- Midlatitude Deciduous
- Southern Pine Forest
- Subtropical Broadleaf Evergreen Forest

Figure B-1 shows the eight CONUS sub-biomes representing the natural vegetation of CONUS. These sub-biomes also represent most of Europe and Southwest Asia (excluding the Saudi Arabian Peninsula), the midlatitudes of Asia including a large portion of China, temperate latitudes of South America and Australia/New Zealand, and selected portions of North and South Africa.

As the study progressed, additional funding allowed the scope of the field collection to be expanded. The subsequent addition of the Boreal Forest, Tropical Rainforest, Montane Forest (a high-altitude tropical environment), and Wet and Dry (Monsoon) tropical sub-biomes to the study provided representative field information for the majority of equatorial and sub-polar vegetation types. When combined with the original eight sub-biomes, approximately two-thirds of the world's natural vegetation cover and all the major MRC areas are represented. The addition of Panama ensured the Central America MRCs would be accurately depicted. The remaining global sub-biomes were not evaluated in the study because they fell into one of the following categories:

- Climates void or nearly void of vegetation. These include several desert sub-biomes, and several arctic sub-biomes.
- Areas that are small, unique, and located where the US Army is unlikely to deploy soldiers. These include the Great Lakes area and northern Siberia.
- Sub-biomes of future importance were eliminated due to prohibitive cost or restricted access.

Military reservations, national parks, state parks, and private property were used for the field collection.

Thirteen sub-biomes and 15 geographic areas were visited during the field data collection. Table B-1 depicts the locations along with their sub-biome and climate definitions (if differentiated). Table B-1 also offers a generalized or descriptive classification of the vegetation found in each of the sub-biome locations. Appendix C provides a general description of world climates with a link to each field collection location. Appendix D provides a description of the vegetation sub-biomes represented within the study.

Table B-1. Vegetative Sub-Biome/Climate and Vegetation Definitions of Data Collection Locations		
Location	Sub-Biome/Climate Type	Vegetation Description
Panama - Gamboa	Monsoon Tropical/Tropical Wet-and-Dry	Monsoon (Rainforest) - Tropical Deciduous Forest
Panama - Fort Sherman	Tropical Rainforest/Tropic Wet	Monsoon (Rainforest) - Tropical Deciduous Forest
Panama - El Valle	Montane Forest/Tropic Upland	Equatorial and Tropical Rainforest - selva, broadleaf evergreen forest
Eglin AFB	Subtropical Broadleaf Evergreen Forest/Humid Subtropical	Oak and Pine Forest with some tropical vegetation
Fort Hood	Dry Steppe (tall grass)	Tall Grass Prairie
Fort Carson	Dry Steppe (short grass)	Short Grass Prairie
Fort Hunter-Liggett	Sclerophyllus vegetation/Mediterranean	Old Oak Forest
Fort Lewis	Coastal Forest/Temperate Oceanic (Marine)	Coastal Forest - largely needleleaf evergreen forest
Fort Benning	Southern Pine Forest/Temperate (warm summer)	Southern Pine and Oak Forest
Smoky Mountains	Midlatitude Deciduous Forest/Temperate (warm summer)	Mixed Deciduous Forest
Willow Grove NAS	Midlatitude Deciduous Forest/Temperate (warm summer)	Mixed Deciduous Forest
Natchaug SF	Midlatitude Deciduous Forest/Temperate (cool summer)	Mixed Deciduous Forest
Fort Drum	Mixed Boreal and Deciduous Forest/Temperate (cool summer)	Mixed Deciduous and Pine Forest
Canada - Gagetown	Mixed Boreal and Deciduous Forest/Temperate (cool summer)	Mixed Deciduous and Pine Forest
Fort Greely	Boreal and Taiga	Mixed Spruce, Birch and Aspen

Former Yugoslavia and Korea Analog Analysis

Based on current world situation, two potential areas for US deployment are the former Yugoslavia and Korea. Since the data collection team was not able to visit either place, US sites closely representing these areas were selected using climate-vegetation analog analysis.

The purpose of this analysis was to find, in CONUS, analogous climates for sites in Korea and former Yugoslavia. It was anticipated tree species could be inferred for locations OCONUS based on the vegetation existing in their US counterparts. Although this seems direct at first, a closer examination of the task revealed common climate classification schemes (e.g., Köppen, Trewartha, etc.) were too broad and generalized in terms of the climatic variables to be used in selecting analogous CONUS sites. Therefore, individual variables used in the past to link climate and vegetation were employed. This is not to imply climate is the only variable regulating the existence of certain tree species at a particular location. Elements such as soils, solar radiation, local water table, competition from other species, latitude, and slope all play a role. However, climatic variables were used as an initial starting point.

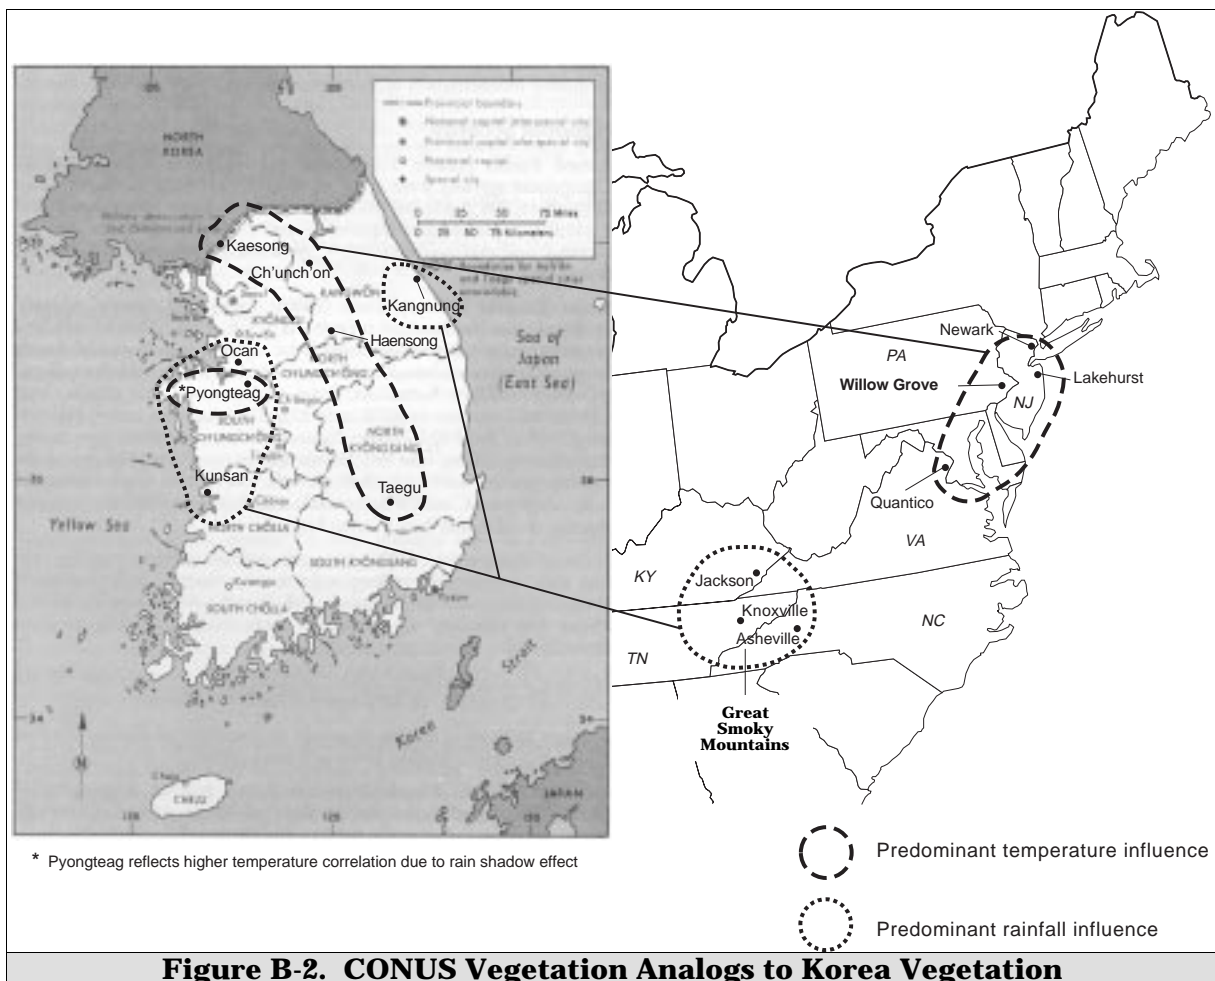

The variables selected were: altitude, mean annual precipitation, mean annual temperature, potential evapotranspiration (PE), and moisture index (MI). The PE provides an indication of the evaporation (expressed in millimeters of water) based on temperature. The MI provides an indication of the moisture regime at a location. These two variables are derived from mean monthly precipitation and temperature. The PE and MI are used by a number of researchers to identify boundaries within which certain vegetation species exist.

The CONUS data set consisted of 176 meteorological stations in the eastern portion of the US. The entire data set containing the five variables for the CONUS stations was used to determine the most closely analogous OCONUS stations. In an optimal scenario, all variables for analogous stations would be compatible. However, during the analysis, it became clear this was not a realistic expectation. In a number of instances, candidate CONUS stations were selected for consideration although certain variables were not perfect matches. For example, in Korea, elevation and continentality were incompatible with many vegetated US stations. It was decided to use the more representative variables of temperature and precipitation in the selection process. Although somewhat subjective, a good deal of climatological reasoning was employed to ensure the candidate analogous CONUS stations were closely representative to the OCONUS stations.

Finally, an analysis of various anomalies was conducted. One difficulty encountered was that stations in Korea might experience a distinct summer monsoon season. Consequently, most Korean locations are especially influenced by either precipitation (pronounced monsoon) or temperature (less pronounced monsoon) criteria. Monthly precipitation values for the months of July through October at many Korean sites may

be more than three to four times the value of any non-monsoon month. On a monthly basis, there is no direct precipitation analog to any site in the entire US, although annual totals are comparable to certain eastern US sites. As previously mentioned, Korean stations also have high continentality indices comparable to those in the north central Great Plains of the US. This is due in part to the dominance of wintertime Siberian high pressure. Similar differences were noted between stations towards the coast of the former Yugoslavia and those further inland exhibiting more continental characteristics.

To better characterize these differences, two representative CONUS stations were chosen for both the former Yugoslavia and Korean sites. Further analysis of the OCONUS sites criteria revealed a good overall correlation to these dual eastern US locations. Figure B-2 depicts the results of the analysis used to determine the Korean analogs. Based on these findings, data were collected in the Smoky Mountains to represent the precipitation influence and at Willow Grove NAS to represent the temperature influence. Figure B-3 depicts the results of the former Yugoslavia analog analysis. Fort Drum was selected for collection to represent the continental influence and northeastern Connecticut was selected to represent the coastal influence.

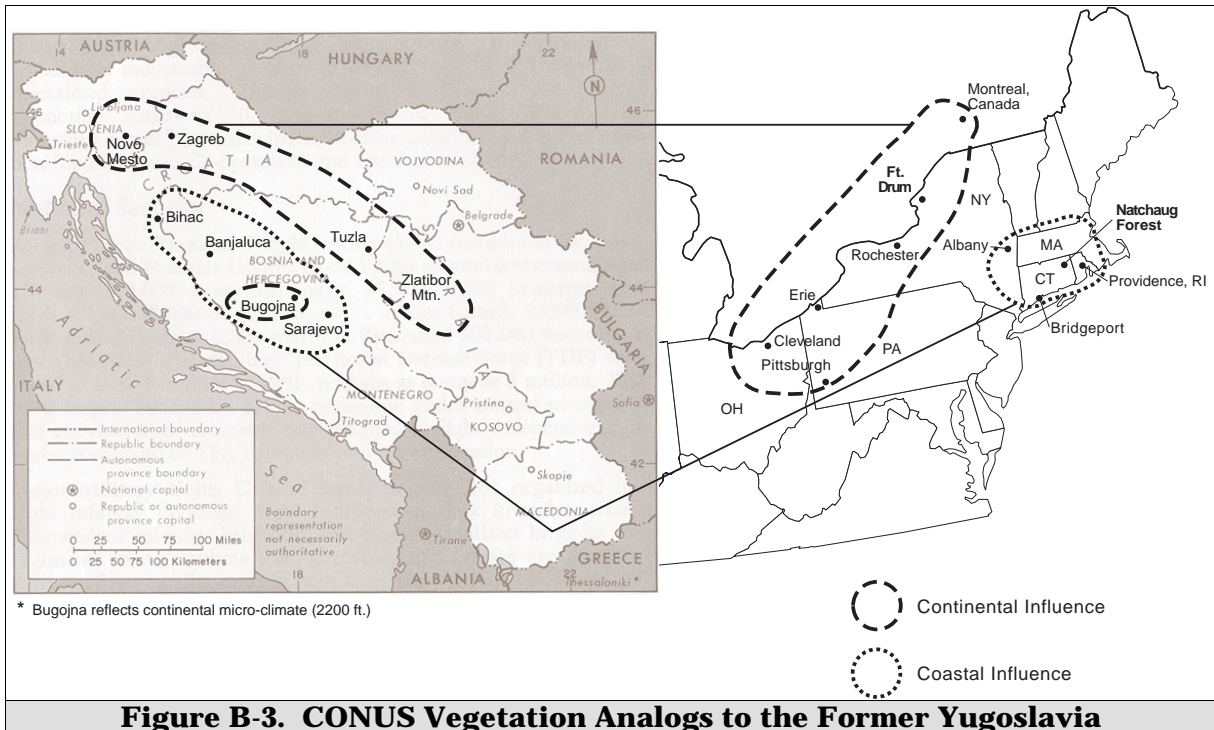

Figure B-3. CONUS Vegetation Analogs to the Former Yugoslavia

Location and Site Description

A general description of each geographic area is included for each data collection location. Places in the world with similar vegetation characteristics are also recorded for each collection location. The collection locations are subdivided into the individual collection sites. The data collected include a description of each data collection site, a description of the undergrowth, whether or not a tank could operate in the area, and the number of azimuths along which data were collected. The number of azimuths varied between four and nine depending on the tactical FOV, the distance along the azimuths, the time available to the data collectors, and weather conditions.

Table B-2 describes the location of the 15 sites to the nearest longitude and latitude and the horizontal datum.

Table B-2. Location of Field Collection Locations		
	Approximate Latitude/Longitude	Horizontal Datum
Panama – Gamboa	79 W, 9 N	NAD 27
Panama – Fort Sherman	79 W, 9 N	NAD 27
Panama – El Valle	79 W, 9 N	NAD 27
Eglin AFB	86 W, 30 N	NAD 27

Table B-3 provides the associated vegetative biome/climate, annual rainfall data, and the dates of the field collection for each geographic area evaluated for the study. A detailed description of the vegetative biomes and climates can be found in appendices C and D, respectively. The average rainfall was determined by examining and compiling data from a number of rainfall stations near each geographic location.

Table B-3. Climate Information About Data Collection Locations			
Location	Climate	Annual Rainfall (Inches)	Collection Dates
Panama – Gamboa	Tropical Wet and Dry	50-60	10-12 March 1998 and 6-12 January 1999
Panama – Fort Sherman	Tropical Wet	110-120	13-16 March 1998 and 7-8 January 1999
Panama – El Valle	Tropical Upland	120-130	18 March 1998 and 5 January 1999
Eglin AFB	Subtropical Humid	60-65	22-25 June 1998
Fort Hood	Semiarid Tall Grass	30-35	30 Sep 97-3 October 1997

*** warm summer/cool winter*

Several (usually four) different sites within each geographic area were selected for data collection. Table B-4 summarizes the individual collection sites. The site identification (ID) is typically an abbreviation of the geographic site and a training range identifier. The exceptions to this notation are Fort Hood, all the Panama locations, Natchaug State Forest, the Smoky Mountains, and Willow Grove NAS. These sites were given an abbreviation and a numerical designator. Table B-4 also includes a mapsheet series and number for each site along with its respective easting, northing, and elevation. The position information was collected in universal transverse mercator (UTM) coordinates using a precision lightweight Global Positioning System (GPS) receiver (precision lightweight GPS receiver (PLGR)) with a 5-7 meter absolute horizontal accuracy.

Table B-5 shows the typical vegetation found at each geographic area. The vegetation/tree types at each area were delineated using a "Field Guide to Trees." A general description of the undergrowth, the undergrowth density, maximum and mean undergrowth height, and canopy closure were subjectively estimated by the data collection team. The canopy closure was the average of the canopy closure for all observers looking in five directions (straight up and looking up at 45-degree angles towards the north, south, east, and west). The overall average is presented in this appendix to the nearest 5 percent.

Table B-5. Canopy Closure, Tree Types, and Undergrowth Information for all Data Collection Sites

** The undergrowth in these areas is undistinguishable from the mature vegetation.*

Geographic Study Areas

The following sections describe each geographic study area visited during the study.

Panama

Six areas from Panama were selected for data collection. Three sites were located in Gamboa, two near Fort Sherman, and one site was in El Valle. Since these sites were all located in a tropical environment, they will be discussed under one heading (Panama) and divided into three separate vegetative/climate biomes.

The Gamboa and Fort Sherman sites were all very close to sea level, while the El Valle site was at a higher elevation (over 700 meters above sea level). Gamboa and Fort Sherman were divided into two different vegetation/climate types based on rainfall. The Fort Sherman area is designated as Tropical Rainforest in a Tropical Wet climate. This area receives rainfall throughout the year while Gamboa has a very distinct dry season (February to April). The vegetation/climate designation for the Gamboa area is Monsoon Forest in a Tropical Wet-and-Dry climate. The vegetation types found at Gamboa and Fort Sherman were similar.

The Fort Sherman sites receive more annual rainfall than the Gamboa sites and the rain is not interrupted by a dry season. However, the undergrowth at Fort Sherman was less dense. It is not completely understood why the undergrowth is thinner at Fort Sherman. One partial explanation is the thicker canopy at Fort Sherman may prevent sunlight to the undergrowth.

The vegetation/climate designation for El Valle is Montane Forest in a Tropical Upland climate. This area contained more broadleaf trees and fewer palms than the lowland sites. The El Valle site is of interest since it shows upland tropical climates (in

the 2,000 to 3,000 foot range) can present concealment rates approaching those of the jungle.

Data were collected from Panama twice. The first data collection coincided with the end of the worst drought in over 100 years. Because the vegetation appeared dry and sparse during the first data collection, data were collected a second time at the end of Panama's rainy season. Surprisingly, the visibility during the two trips was virtually equal. The differences in the fitted curves for the El Valle site for the two trips are less than 1 percent across all ranges. The vegetation parameters for the sites at Gamboa and Fort Sherman indicate that the vegetation was slightly denser the second trip. However, the difference was undistinguishable by the data collection team and was apparent only after the data were analyzed and plotted. The analysis showed that for the two visits, the difference between corresponding best fit curves, for any given range, was always less than 5 percent.

Panama (Monsoon Forest/Tropical Wet-Dry Climate). Three sites in close proximity, designated gam1, gam2, and gam3, were selected near the town of Gamboa. This is located on the Pacific Ocean side of Panama.

Other areas in the world with similar vegetation characteristics include the Pacific coasts of Honduras, Nicaragua, Costa Rica, and Panama; Haiti; the leeward portions of Puerto Rico and Cuba; northeast India, the border area between Viet Nam and China; northern Thailand, Laos, and Cambodia; northern Australia between 10 and 20 degrees south latitude; portions of eastern and southern Brazil, eastern Bolivia, and central Venezuela; and a large portion of subequatorial Africa including Angola, Zambia, northern Namibia, and Botswana.

- Number of Azimuths:
 - gam1: 4
 - gam2: 8
 - gam3: 8
- Vegetation Types: Palms, vines, and some broadleaf trees
- Undergrowth Description: The undergrowth was not distinguishable from the trees
- Could a Tank Operate in This Area: No, very thick jungle vegetation

Panama (Tropical Rainforest/Tropical Wet Climate). The two sites at Fort Sherman are located on the Atlantic side of the country. The data were collected at sites named Skunk Hollow (skh1) and McKenzie Range (mck1).

Other areas in the world with similar vegetation characteristics include the Atlantic coasts of Honduras, Nicaragua, Costa Rica, and Panama; lowland portions of Guatemala, Belize, and portions of south-central Mexico; the Dominican Republic; the windward coasts of Puerto Rico and Cuba; northern Columbia, the interior and southeast coast of Brazil; Malaysia; most of Viet Nam; central Thailand; the

Philippines; most of Indonesia and southwest India; northeast coast of Australia; eastern Madagascar; the Congo; Gabon; and northern Zaire.

- Number of Azimuths:
skh1: 5
mck1: 7
- Undergrowth Description: The undergrowth was not distinguishable from the trees
- Could a Tank Operate in This Area: No, very thick jungle vegetation

Panama (Montane Forest/Tropical Uplands Climate). El Valle is a high altitude tropical environment located about 150 miles west of the Canal Zone. Data were collected at one site here.

Other areas in the world with similar vegetation characteristics include Nepal, Bhutan, southern China, inland New Guinea, and upland areas of Borneo and Sumatra; highlands of Kenya, Zaire, Tanzania, Malawi and central Ethiopia; central Peru and upland areas of Guatemala, Nicaragua, Costa Rica, and Honduras.

- Number of Azimuths: 6
- Vegetation Types: Mostly broadleaf trees. There were some evergreen trees in the general area, but none where the data were collected
- Undergrowth Description: The undergrowth was not distinguishable from the trees
- Could a Tank Operate in This Area: No, very thick jungle vegetation

Eglin Air Force Base (AFB), FL

Four sites from Eglin AFB were selected for data collection. The vegetation/climate designation for this area is Subtropical Broadleaf Evergreen Forest in a humid subtropical climate. The vegetation at Eglin AFB can be divided into two distinct types: Xeric and Baygall. Evergreen oaks with a thick canopy are typical of Xeric vegetation. Xeric vegetation is associated with dry, sandy soils. Baygall is characterized by dense, broadleafed evergreen shrubs and trees. Baygall typically occurs in wet soils such as depressions and floodplains. Sites representative of Xeric vegetation have been given an 'X' designation and sites representative of Baygall have been given a 'B' designation.

Other areas in the world with similar vegetation characteristics include the southern tip of South Korea, south Japan, and the southeast third of China; northern New Zealand, and portions of southeastern coastal Australia including the island of Tasmania.

egl_B2. This Baygall site was located on the northwest corner of Eglin AFB in a swampy area.

- Number of Azimuths: 8

- Undergrowth Description: Ferns, bushes, and tropical plants
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

egl_X8. This Xeric site was located east of the main base in an area between state highway 20 and the Choctawhatchee Bay.

- Number of Azimuths: 7
- Undergrowth Description: Small bushes
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

egl_X11 This Xeric site was located next to the Basin Bayou east of the Eglin AFB main base.

- Number of Azimuths: 7
- Undergrowth Description: Ferns, palms, vines, and tropical plants
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

egl_B12. This Baygall site was located east of Eglin AFB in a swampy area south of a service road less than two miles north of the Choctawhatchee Bay.

- Number of Azimuths: 8
- Undergrowth Description: Small palms, small trees, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Fort Hood, TX

Four sites were selected on the Fort Hood military reservation. The vegetation/climate designation for this area is Tall Grass Prairie. There were three typical areas of sparse vegetation and one area with dense vegetation. The area of dense vegetation was selected to replicate a generic tropical environment. Data were collected at a time when it appeared funds would be unavailable to visit an actual tropical environment.

Other areas in the world with similar vegetation characteristics include Uruguay, eastern Argentina, eastern New Zealand, southeast Poland, eastern Hungary, and the Slovak Republic.

hood1. This site was located in the southeast portion of Fort Hood just south of Belton Reservoir. The vegetation is homogeneous and is representative of the majority of the post.

- Number of Azimuths: 6

- Undergrowth Description: Very sparse undergrowth made up of grasses and young trees (juniper)
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced

hood2. This site was located in the northwest portion of Fort Hood on some of the higher terrain on the post. There is a mix of vegetation common for Fort Hood.

- Number of Azimuths: 9
- Undergrowth Description: Sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced

hood3. This area was located in the northwest area of Fort Hood. It is an isolated area and is atypical because of the high density vegetation. There were places in the area so dense a soldier could not stand up straight. Data were collected early in the study when collecting data in a tropical climate seemed improbable. This site was selected to depict a tropical environment.

- Number of Azimuths: 6
- Undergrowth Description: Very thick. The undergrowth was made up of small trees and bushes
- Could a Tank Operate in This Area: No, the vegetation is too dense

hood4. The data collection team returned to the hood1 site and selected an area approximately 100 meters from hood1. This was done in order to attempt to replicate the data from the previous site.

- Number of Azimuths: 8
- Undergrowth Description: Very sparse undergrowth made up of grasses and young trees (scrub oak)
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees were widely spaced

Fort Carson, CO

Three areas from Fort Carson and one area from the Air Force Academy (AFA) were selected for data collection. The vegetation/climate designation for this area is Short Grass Prairie. The sites at Fort Carson contained medium density vegetation, while the AFA site provided a denser area of vegetation. All four sites were located at high altitudes (approximately 2,000 meters).

Other areas in the world with similar vegetation characteristics include parts of South Africa, interior Turkey, northern Iraq and Syria, parts of northern China, and in Russia from north of Mongolia west to the Black Sea at 50 degrees north latitude. The AFA site is similar to the higher elevations of north central China and the Caucasus area of northern Turkey.

car41. This site was along the western edge of Fort Carson in the foothills of the Rocky Mountains.

- Number of Azimuths: 9
- Undergrowth Description: Very sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced

car43. This site was along the southern part of Fort Carson on one of several plateaus.

- Number of Azimuths: 7
- Undergrowth Description: Very sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced

car28. This site was along the central portion of Fort Carson just west of the artillery impact area.

- Number of Azimuths: 8
- Undergrowth Description: Very sparse undergrowth made up of grasses and some deadfall
- Could a Tank Operate in This Area: Yes, but there would be limited mobility due to the density of low-branching trees (average "height of lowest branch" is 2 to 3 meters above the ground)

afa1. This area was located north of North-Gate Boulevard in the northeast portion of the AFA. All of the previous three sites represent Fort Carson vegetation very well. However, the AFA site provided a different vegetation type. Although Fort Carson and the AFA are located less than 10 miles apart and elevations are comparable, they exhibit very different vegetation and climate characteristics. While Fort Carson can be described as a Short Grass Prairie climate (or Steppe), the AFA is in an area which transitions to a boreal vegetation and climate zone. This is the result of the unique geography in the area causing increased rainfall and cooler temperatures.

- Number of Azimuths: 7
- Undergrowth Description: Very sparse undergrowth made up of grasses and small scrub oaks
- Could a Tank Operate in This Area: No, too many large trees are spaced closely together

Fort Hunter-Liggett, CA

Four sites from Fort Hunter-Liggett were selected for data collection. The vegetation/climate designation for this area is Sclerophyllous forest (better known as "chaparral") with a Mediterranean climate. The sites were primarily populated with old, widely scattered live oak, some grasses, and scrub.

Other areas in the world with similar vegetation characteristics include the Mediterranean region of Europe (southeast Spain, southern France (Riviera), Sicily, Corsica, Sardinia, all of coastal Italy inland to the Appenines, Greece and coastal Turkey), the North African coast from Libya to Morocco, and southwest Australia.

hl2. This site was located at the northern edge of Fort Hunter-Liggett at the boundary with the Los Padres National Forest.

- Number of Azimuths: 8
- Undergrowth Description: Very sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced; however, mobility would be impaired because tree limbs are about 2 meters above the ground

hl5. This site was located at the northwest part of Fort Hunter-Liggett.

- Number of Azimuths: 8
- Undergrowth Description: Very sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced; however, mobility would be impaired because tree limbs are about 2 meters above the ground

hl10. This site was located at the northeast edge of Fort Hunter-Liggett.

- Number of Azimuths: 8
- Undergrowth Description: Sparse undergrowth made up of grasses
- Could a Tank Operate in This Area: Yes, there is virtually no undergrowth and the trees are widely spaced; however, mobility would be impaired because tree limbs are about 2 meters above the ground

hl9. This site was located near the center of Fort Hunter-Liggett about 4 kilometers south of the main post area.

- Number of Azimuths: 6
- Undergrowth Description: Moderate undergrowth made up of grasses and several dead trees.
- Could a Tank Operate in This Area: Yes, there is some undergrowth but the trees are widely spaced. Mobility would be impaired because dead trees and tree limbs are about 2 meters above the ground

Fort Lewis, WA

Four areas from Fort Lewis were selected for data collection. The vegetation/climate designation for this area is Coastal Forest/Marine West Coast climate. All sites were densely vegetated.

Other areas in the world with similar vegetation characteristics include portions of the northwestern US, southern British Columbia, the western coast of Canada, and southeastern Alaska.

lew10. This site was along the east edge of Fort Lewis.

- Number of Azimuths: 6
- Undergrowth Description: Very dense undergrowth made up of small trees, ferns, shrubs, and deadfall
- Could a Tank Operate in This Area: No, the undergrowth is too thick for any type of vehicles; even dismounted units would have trouble with mobility in this area

lew19. This site was along the southwest corner of Fort Lewis just to the southwest of the artillery impact area.

- Number of Azimuths: 8
- Undergrowth Description: Very dense undergrowth made up of small trees, ferns, shrubs, and deadfall
- Could a Tank Operate in This Area: No, the undergrowth is too thick for any type of vehicles. Even dismounted units would have trouble with mobility in this area

lew3. This site was in the western part of Fort Lewis just east of the Nisqually River.

- Number of Azimuths: 8
- Undergrowth Description: Very dense undergrowth made up of small trees, ferns, shrubs, and deadfall
- Could a Tank Operate in This Area: No, the undergrowth is too thick for any type of vehicles. Even dismounted units would have trouble with mobility in this area

lew8. This site was along the east edge of Fort Lewis 2 kilometers north of lew10.

- Number of Azimuths: 8
- Undergrowth Description: Very dense undergrowth made up of small trees, ferns, shrubs, and deadfall
- Could a Tank Operate in This Area: No, the undergrowth is too thick for any type of vehicles. Even dismounted units would have trouble with mobility in this area

Fort Benning, GA

Four areas from Fort Benning were selected for data collection and are representative of the entire area. The vegetation/climate designation for this area is Southern Pine Forest in a temperate (warm summer/cool winter) climate. All of these

sites were selected in the central part of the training ranges to avoid impact areas and Army Training and Evaluation Program (ARTEP) training.

Other areas in the world with similar vegetation characteristics include the southeast and gulf coast regions of the US.

ben_T3. This site was located in a flat area between Selby Hill and Wadsworth Hill.

- Number of Azimuths: 5
- Undergrowth Description: Scrub oak, small trees and bushes, vines
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

ben_L3. This site was located in a large flat area west of the Upatoi River.

- Number of Azimuths: 8
- Undergrowth Description: Small trees and bushes, deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

ben_T4. This site was located south of Rockwell Hill just off First Division Road.

- Number of Azimuths: 8
- Undergrowth Description: Small trees and bushes
- Could a Tank Operate in this Area: No, the trees are spaced too close together for a tank to operate

ben_D12. This site was along the east edge of Fort Benning near the intersection of Hourglass Road and Buffalo Road.

- Number of Azimuths: 8
- Undergrowth Description: Small trees and bushes
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Great Smoky Mountains National Park, NC and TN

Four areas from the Smoky Mountains were selected for data collection. The vegetation/climate designation for this area is Midlatitude Deciduous Forest in a temperate (warm summer/cool winter) climate. The Smoky Mountains are located along the NC/TN border. This park was selected for data collection because its vegetation/climate are similar to those regions of Korea with pronounced monsoon (predominant rainfall influence) characteristics.

Other areas in the world with similar vegetation characteristics include most of South Korea, North Korea, the country of Georgia, portions of central Russia between

50 and 55 degrees north latitude, northern Iran, the Caucasus Mountains, England, Ireland, Wales, most of Scotland, France, northern Spain, most of Germany, most of the Czech Republic, western Hungary, Bulgaria, and southern Romania.

NC1. This site was to the northwest of the Cataloochee Divide. It is behind a gated area southwest of the ranger station and at the end of a long open field.

- Number of Azimuths: 7
- Undergrowth Description: Bushes, deadfall, and small elms and pines
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

TN1. This site was located in the Greenbriar State Recreation Area of the Smoky Mountains approximately 8 miles east of Gatlinburg, TN. It is next to the Little Pigeon River and close to the ranger station.

- Number of Azimuths: 8
- Undergrowth Description: Ferns, deadfall, and small trees
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

TN2. This area was to the southeast of Sugarlands on the northeast side of an old rock wall. This area was an agricultural area before the national park was established. The agriculture was abandoned and the area has been forested since the 1940s.

- Number of Azimuths: 7
- Undergrowth Description: Ferns, deadfall, and small trees
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

TN3. This area was located at the northeast end of Big Springs Cove. It is located east of Laurel Creek Road in a recreational area.

- Number of Azimuths: 6
- Undergrowth Description: Deadfall and widely scattered small trees
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Willow Grove NAS, PA

Willow Grove NAS is located north of Philadelphia, PA. Four areas from Willow Grove NAS were selected for data collection. The vegetation/climate designation for this area is Midlatitude Deciduous Forest in a temperate (warm summer/cool winter) climate. This area was selected for data collection because its vegetation/climate are similar to those regions of Korea with less pronounced monsoon (predominant temperature influence) characteristics.

Other areas in the world with similar vegetation characteristics include most of South Korea, North Korea, the country of Georgia, portions of central Russia between 50 and 55 degrees north latitude, northern Iran, the Caucasus Mountains, England, Ireland, Wales, most of Scotland, France, northern Spain, most of Germany, most of the Czech Republic, western Hungary, and southern Romania.

WG6. This site was located at the former US Naval Air Development Center. It is located in a wooded area south of the eastern end of the runway.

- Number of Azimuths: 6
- Undergrowth Description: Bushes, vines, and thick grass
- Could a Tank Operate in This Area: Probably, the trees are spaced far enough apart for a tank to operate in this area

WG2. This site was located at a corner near the picnic area at Willow Grove NAS.

- Number of Azimuths: 7
- Undergrowth Description: Bushes and vines
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

WG5. This area belongs to the town of Willow Grove. The site selected was just north of the police firing range.

- Number of Azimuths: 7
- Undergrowth Description: Bushes, vines, small trees, and thick grass
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

WG4. This area belongs to the city of Willow Grove. It was located southwest of the Graeme Historical Site.

- Number of Azimuths: 6
- Undergrowth Description: Bushes and vines
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Natchaug State Forest, CT

Four areas from Natchaug State Forest were selected for collection. Natchaug State Forest is made up of small, disjointed parcels of land scattered about the northeast portion of the state. The vegetation/climate designation for this area is Midlatitude Deciduous Forest in a temperate (cool summer/cold winter) climate. This park was selected for data collection because its vegetation/climate are similar to those regions of Bosnia and the former Yugoslavia which are closer to the Adriatic coast.

Other areas in the world with similar vegetation characteristics include most of South Korea, North Korea, the country of Georgia, portions of central Russia between 50 and 55 degrees north latitude, northern Iran, the Caucasus Mountains, England, Ireland, Wales, most of Scotland, France, northern Spain, most of Germany, most of the Czech Republic, western Hungary, Bulgaria, and southern Romania.

Nat2. This site was located north of Summer Lane west of an old rock wall.

- Number of Azimuths: 4
- Undergrowth Description: Ferns, small shrubs, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Nat1. This site was located at the end of Laurel Lane to southwest of a recreational vehicle park.

- Number of Azimuths: 6
- Undergrowth Description: Ferns, mountain laurel, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Nat4. This site was located west of Pumpkin Road.

- Number of Azimuths: 8
- Undergrowth Description: Ferns, scattered small shrubs, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Nat5. This site was located north of Station Road.

- Number of Azimuths: 5
- Undergrowth Description: Mostly ferns with some small trees
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Fort Drum, NY

Four areas from Fort Drum were selected for data collection. The vegetation/climate designation for this area is Mixed Boreal and Deciduous Forest in a temperate (cool summer/cold winter) climate. Fort Drum was selected as a data collection location because its vegetation/climate are similar to those regions in the interior of Bosnia and adjacent portions of former Yugoslavia. The data collection was limited to the southern portion of Fort Drum because a large ice storm in January 1998 destroyed or changed the typical vegetation for most of the fort.

Other areas in the world with similar vegetation characteristics include southern Chile, northeast China, northern Japan, Estonia, Latvia, Lithuania, most of

Switzerland, western Austria, southeastern Germany, western regions of the Czech Republic, southern Poland, and northern Romania.

8C. This site was located near Lake School Road.

- Number of Azimuths: 8
- Undergrowth Description: Ferns, small trees, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

7G. This site was located in a large flat area just north of Ward Hill.

- Number of Azimuths: 8
- Undergrowth Description: Ground cover, small trees, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

7B. This site was located north of a park north of state highway 3A.

- Number of Azimuths: 8
- Undergrowth Description: Bushes and small trees
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

7E. This site was located north of Barr Hill just south of state highway 3A.

- Number of Azimuths: 6
- Undergrowth Description: Ferns, small trees, deadfall, and ground cover
- Could a Tank Operate in this Area: No, the trees are spaced too close together for a tank to operate

Gagetown Canadian Forces Base, New Brunswick, Canada

Four areas from Gagetown were selected for data collection in order to assist the Canadian modeling and simulation program. The vegetation/climate designation for this area is Mixed Boreal and Deciduous Forest in a temperate (cool summer/cold winter) climate.

Other areas in the world with similar vegetation characteristics include southern Chile, northeast China, northern Japan, Estonia, Latvia, Lithuania, most of Switzerland, western Austria, southeastern Germany, western regions of the Czech Republic, southern Poland, and northern Romania.

Gage31. This site was located on McCutcheon Road south of the impact area.

- Number of Azimuths: 5
- Undergrowth Description: Mostly ferns with some deadfall

- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Gage27. This site was located on the southeast corner of the post near the Saint John River.

- Number of Azimuths: 7
- Undergrowth Description: Ferns, small trees, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Gage8. This site was located along Shirley Road in the northeast portion of post.

- Number of Azimuths: 8
- Undergrowth Description: Small trees and ferns
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Gage7. This site was located along Shirley Road in the northeast portion of post.

- Number of Azimuths: 6
- Undergrowth Description: Small trees
- Could a Tank Operate in This Area: Possibly, the trees are scattered in spots and thin

Fort Greely, AK

Six areas from the eastern half of Fort Greely were selected for data collection. The vegetation/climate designation for this area is Boreal Forest/Taiga. The vegetation at Fort Greely can be equally divided into three distinct types: evergreen, deciduous, and mixed. The evergreen areas are exclusively black spruce. The deciduous areas are white birch or aspen. There were also areas at Fort Greely with a mixture of evergreen and deciduous trees. Data were collected at two areas for each of the three vegetation types. Sites G05 and G02 were located along 33 Mile Loop, sites G22 and G00 were located along the main supply route (MSR), and sites G24 and G25 were located close to the main post.

Other areas in the world with similar vegetation characteristics include northern Canada, mountainous areas of the western US, central Alaska, Finland, Sweden, the Swiss/Italian Alps, coastal Norway, northern Japan, western and central Russia between 55 and 65 degrees north latitude, the pacific coast of Russia, portions of western China (including Tibet and the Himalayan region), high altitude areas of Indonesia, upland areas of northern Peru, northern Chile, Bolivia, Argentina, and the Atlas mountains of Africa.

G22. This site was located south of the main post near a pumping station and next to the MSR road.

- Number of Azimuths: 6
- Undergrowth Description: Small deciduous bushes
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

G00. This site was located at the southern portion of Fort Greely next to the MSR road.

- Number of Azimuths: 7
- Undergrowth Description: Small black spruce and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

G25. This site was located about 1 kilometer south of the main housing area at Fort Greely.

- Number of Azimuths: 8
- Undergrowth Description: Small spruce, deadfall, and small bushes
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

G02. This site was located east of Jarvis Creek and west of Buffalo Drop Zone.

- Number of Azimuths: 8
- Undergrowth Description: Small spruce, shrubs, and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

G24. This site was located east of the housing area and west of Jarvis Creek.

- Number of Azimuths: 8
- Undergrowth Description: Small spruce and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

G05. This site was located along 33 Mile Loop north of the Eddy Landing Zone/Drop Zone.

- Number of Azimuths: 8
- Undergrowth Description: Small spruce and deadfall
- Could a Tank Operate in This Area: No, the trees are spaced too close together for a tank to operate

Appendix C. Climates

Introduction

Climate may be defined as a composite of the long-term prevailing weather occurring at a location. It is the normal reoccurring weather pattern, with some small variations perhaps, from year to year. This appendix discusses the different climate types evaluated in this study. It is not the intent within this section to provide a climate primer with very detailed climate definitions but rather to offer a general guide to facilitate ease of use by model developers.

Climate Types

The earliest climatic classification schemes were based solely on temperature. The early Greeks divided the world into three zones – torrid, temperate, and frigid. Throughout the centuries this scheme was modified by others to reflect seasonal variations of temperature – e.g., cool summers, warm summers, warm winters, cold winters, etc. Precipitation was then added to the classification to reflect the moisture characteristics of regions. This was especially true in the differentiation of arid climates. Classifications based on these two elements, temperature and precipitation (moisture), are the most numerous in the literature; the schemes of Köppen and Trewartha are the dominant ones in use today. Other classifications have added additional elements (e.g., solar radiation, air mass frequencies, evaporation, etc.) to further define and subdivide regions based on similar climate characteristics. Many classification schemes have as their basis the regional distribution of natural vegetation. Listed from the equator to the poles, they are: tropical, dry, subtropical, temperate, boreal, and polar. Most have significant subdivisions, which are also discussed.

Tropical Climates

Tropical climates (sometimes referred to as **Equatorial** climates) are found straddling the equator generally between 23.5 degrees north (N) latitude (Tropic of Cancer) and 23.5 degrees south (S) latitude (Tropic of Capricorn). They tend to be somewhat wider on the eastern side of continents than on the western side. These climates cover about 25 percent of the surface of the land. Areas within the tropical climates experience frost-free conditions year-round and each month has an average temperature of over 65° Fahrenheit (F) (18° Celsius (C)). In addition to warm temperatures, the yearly rainfall is generally over 70 inches and can be substantially more (over 100 inches). The tropical climates can be divided into two subtypes: **tropical wet** and **tropical wet-and-dry**.

The **tropical wet** climate (sometimes referred to as the *tropical rainforest* climate) is located primarily between 10°N and 10°S latitude and resides in the region

under the influence of the *intertropical convergence zone* (ITCZ). The ITCZ represents the boundary between the northeast and southeast trade winds. Areas experiencing the tropical wet regime account for about 10 percent of the land surface of the earth. Temperatures within this region exhibit little variation from day to day and from month to month. Although the region as a whole has abundant precipitation throughout the year (greater than 70 inches), there are locations experiencing short dry seasons that last for less than 2 months.

The **tropical wet-and-dry** climate is found poleward of the tropical wet climate, extends to approximately 20°N and 20°S, and accounts for approximately 15 percent of the land surface of the earth. Regions with this type climate alternate throughout the year between the influences of the wetter ITCZ and the more stable, drier subtropical anticyclones (areas of high pressure). The tropical wet-and-dry region has a dry season of more than 2 months and the typical annual rainfall is usually between 40 and 60 inches. Temperatures are similar to those experienced in the tropical wet climatic regions. In addition to the two major divisions of the tropical climate, the tropical wet-and-dry subdivision can be further divided into a **tropical upland wet-and-dry** climate. This climate is defined as having elevations of greater than 610 meters (2,000 feet). This differs from tropical wet-and-dry because its higher elevations typically produce lower temperatures.

The data collected in Panama represent all three of the tropical climates. Gamboa is a tropical wet-and-dry climate, Fort Sherman is a tropical wet climate, and El Valle is a tropical upland wet-and-dry climate.

Dry Climates

Dry climates are defined as areas where the annual water loss through evaporation exceeds the annual water gain through precipitation. These climates can be found at almost every latitude and make up approximately 25 percent of the land surface of the earth. They extend from north of the tropical wet-and-dry up to the vicinity of the Arctic Circle (66.5°N latitude). At lower latitudes, dry climates are caused by the dominance of the subtropical anticyclones, which produce generally clear skies. Moving northward, they are found in the interior of continents far away from moisture sources. Dryness here may also be accentuated by mountain ranges producing a rainshadow effect. These more northerly dry areas typically have warmer summers and colder winters than other climates at the same latitude. Dry climates can be subdivided into **desert** and **semiarid (steppe)** subclimates. Desert climates experience an annual rainfall of 10 inches or less, whereas areas of semiarid climate have annual amounts in the range of 15-25 inches. Semiarid climates (also referred to as **grassland** climates) can also be further broken down into tall-grass and short-grass varieties (steppe).

Data collected at Fort Hood (tall-grass) and Fort Carson (short-grass/steppe) represent a dry climate. No data were collected for a desert climate.

Subtropical Climates

Subtropical climates are characterized as having definite seasonal rhythms creating a summer and a winter. Most of the subtropics are subject to an occasional killing frost. Eight months will have an average temperature of over 50 degrees. The subtropics can be divided into two sub-climates: **subtropical dry-summer** climate, often called a **Mediterranean** climate and **subtropical humid** climate, which is also known as **humid subtropical**. The Mediterranean climate is typically located in the middle latitudes at approximately 30-40° latitude and along the western sides of continents. This is a transitional climate, lying between the low-latitude dry climates to the south and the cool, moist marine climates further north. This climate has almost no severe cold weather during the winter season. Average winter temperature are generally between 40 and 50°F (4.5 and 10°C). Summers can be hot, with average summer temperatures between 65 and 80°F (18 and 21°C). The average annual rainfall is usually 15-25 inches with the bulk falling during the winter months.

The subtropical humid climate differs from the Mediterranean climate because it is located on the eastern side of continents, has more annual rainfall (30-60 inches), and the rain falls throughout the year with a maximum occurring during the summer months. The average winter temperature is between 40 and 55°F (4.5 and 12.8°C) and average summer temperatures range from 75 to 80°F (24 to 26.6°C).

Data collected at Fort Hunter-Liggett represents a Mediterranean climate and data collected at Eglin AFB represents a subtropical humid climate.

Temperate Climates

A **temperate** climate is defined as an area where average temperatures are over 50 degrees for four to eight months. There are two subclimates: the **temperate oceanic** and the **temperate continental**. The temperate oceanic, often referred to as **Marine West Coast**, exhibits milder temperature conditions than does the temperate continental. Winters are warmer and summers are cooler than for more continental locations at the same latitude. All months average above freezing. The average rainfall in the temperate oceanic climate varies widely (between 20 and 150 inches), but it is considered to have adequate rainfall for all seasons.

Locations with a temperate continental climate have most of their annual rainfall (20 to 60 inches) during the summer months. This climate can be further subdivided into two more groups: a) temperate continental with warm summer and cool winter and b) temperate continental with a cool summer and a cold winter. An average summer temperature of 72°F (22°C) is used to distinguish between the two subgroups.

Fort Lewis was used to represent the temperate oceanic climate. The temperate continental (warm summer and cool winter) data were collected at the Smoky Mountains, Willow Grove NAS, and Fort Benning. The temperate continental (cool

summer and cold winter) data were collected at Fort Drum, Natchaug State Forest, and Gagetown (Canada).

Boreal Climate

Boreal climates, sometimes referred to as **Continental Subarctic** or **Subpolar** climates, are normally restricted to between 50 and 65 degrees latitude (or high elevations at lower latitudes). They will have an average monthly temperature of at least 50°F (10°C) for 1 to 3 months. The average annual rainfall is usually less than 20 inches and falls during the short summer. The transition zone at which large woody vegetation can no longer exist is known as the "tree line." These zones (also referred to as taiga or alpine tundra) usually occur within the fringes of the boreal climate.

Data were collected at Fort Greely to represent boreal and taiga climates.

Polar Climate

Polar climates, sometimes referred to as **Ice** climates or **Tundra** climates, exist when the average monthly temperature never reaches 50°F (10°C). The average annual precipitation is meager; most stations receive less than 8 to 10 inches. This climate type is usually divided into an area possessing tundra vegetation (mosses, lichen, and small plants) and one possessing a permanent ice cap.

The absence of a growing season dictated that data would not be collected in a polar climate.

Appendix D. Vegetative Sub-Biome Descriptions

This appendix contains definitions and descriptions of the vegetative sub-biomes representing the 15 field data collection locations. Each sub-biome is usually linked to a specific climate (although some occur in multiple climates) with a unique set of vegetation types and patterns. This appendix provides a general guide to typical vegetation and characteristics expected to occur at each vegetative sub-biome location. It is intended to facilitate ease of use by model developers. Figure D-1 (found at the end of this appendix) provides a world map delineated by sub-biome type. The abbreviations after each section heading represent the sub-biome designations identified in figure D-1. While the world is divided into 27 sub-biomes, this appendix concentrates on only the 13 where data were collected. Table D-1 (found at the end of this appendix) provides an alphabetized list of global locations (by continent and country), their corresponding vegetative sub-biomes, and a short discussion regarding the 14 sub-biomes omitted from the study.

Tropical Rainforest (Fe)

Tropical Rainforest consists of closely set trees whose crowns form a continuous canopy of foliage and provide dense shade for the ground and lower layers. The floor of the tropical rainforest is usually densely shaded and plant foliage is often sparse close to the ground. Further up, tree leaves are large and evergreen. Crowns of the trees tend to form into two or three layers, of which the highest layer consists of scattered emergent crowns rising to 40 meters and protruding conspicuously above a second layer, 15 to 30 meters high, which is continuous. A third, lower layer consists of small, slender trees 5 to 15 meters in height with narrow crowns. Typical in this vegetation are thick, woody vines and epiphytes (ferns, orchids, mosses, etc.) supported by the trunks, branches, and foliage of the trees. These vines and ferns often occur in the lower layers of vegetation near the ground, hampering movement and visibility. Another particularly important characteristic of the tropical rainforest is the large number of tree species coexisting; as many as 1,000 species may be found in a square kilometer.

Monsoon Forest (Fmo)

Monsoon Forest presents a more open tree growth than the tropical rainforest. Consequently, there is a greater development of vegetation in the lower layers. Maximum tree heights range from 12 to 35 meters and tree trunks are massive. Branching starts at low levels (compared to the tropical forest) and produces large, round crowns. Many tree species are present and may number 30 to 40 in a small tract. One of the most important aspects of the monsoon forest is the deciduous nature of the tree species present. The shedding of leaves results from the stress of a pronounced dry season occurring at a time of low sun and cooler temperatures. Thus, the monsoon forest in the dry season has a somewhat dormant appearance. Vines and ferns are locally abundant but are fewer and smaller than in the tropical rainforest.

Undergrowth is often a dense shrub thicket. However, where second growth vegetation has formed, the undergrowth is typically jungle.

Montane Forest (Fmt)

Montane Forest exists in regions of tropical rainforest where island-like highlands of cooler climate are found. Between 600 meters and 2,000 meters above sea level, the rainforest gradually changes in structure. Montane Forest has lower tree heights and a less dense canopy than tropical rainforests of adjacent lowlands. Due to the sparse canopy, undergrowth can be very dense and tree ferns and bamboo are numerous.

Broadleaf Evergreen Forest (Fbe)

Broadleaf Evergreen Forest differs from tropical rainforests in having relatively few species of trees. Thus, there are large populations of individuals of a species. Trees are shorter than in the tropical rainforests, the leaves tend to be smaller and more leathery, and the leaf canopy is less dense. Broadleaf evergreen forests tend to have a well-developed lower stratum of vegetation including tree ferns, small palms, bamboo, shrubs, and herbaceous plants. Vines, ferns, and mosses are abundant. An example is the "spanish moss" draping many oak and cypress trees on the Gulf Coast of the southeastern US.

Tall Grass Prairie (Gp)

Tall Grass Prairie consists of tall grasses comprised of dominant herbs and subdominant herbaceous plants. Trees and shrubs are generally sparse, but may occur as forest or woodland patches in valley bottoms or other locations. The grasses are deeply rooted and may form a continuous and dense cover. The grasses peak in spring and the herbaceous plants peak in late summer. In North America, areas of deciduous forest are mixed with areas of tall grass prairie over a large transition belt from the Dakotas to central Texas. The Pampa region of Argentina in South America and the Puszta region of eastern Europe (eastern Hungary/Slovak Republic) are other examples of tall grass prairie.

Short Grass Prairie (Gs)

Short Grass Prairie (also known as Steppe) is comprised of many species of short grasses and herbs occurring in sparsely distributed clumps or bunches. Scattered shrubs and low trees may also be found in the steppe. Ground coverage is small and much bare soil is exposed. Steppe grades into semi-desert in dry environments, into tall grass prairie where rainfall is more abundant, or may give way to deciduous/coniferous forest at higher elevations or latitudes. Steppe vegetation is largely concentrated in vast mid-latitude areas of North America (western plains to the front range of the Rocky Mountains) and Eurasia. Steppe grasses peak in early summer and are usually dormant by mid-summer, although occasional summer rainstorms may cause periods of revived growth.

Sclerophyllous Forest (Also Called Mediterranean/Chaparral Vegetation) (Fss)

Sclerophyllous Forest consists of low trees with small, hard, leathery leaves. Typically, the trees are low-branched and gnarled, with thick bark and canopy coverage of only 25 to 60 percent. Some of this is woodland consisting of "live oak," "white oak," and other similar species. There may also be extensive areas of Sclerophyllous scrub or "dwarf forest/chaparral" having a canopy closure of under 50 percent. This chaparral varies in composition with elevation and exposure. The trees and shrubs are predominantly evergreen; their thickened leaves being retained despite a severe annual drought. There is little stratification in the Sclerophyllous forest and scrub, although there may be a significant grass layer providing substantial ground cover.

Needleleaf/Coniferous Forests

Needleleaf or Coniferous Forests are composed of largely straight-trunked, conical trees with relatively short branches and small, needlelike leaves. Usually evergreen, the coniferous forest provides continuous and deep shade to the ground so lower layers of vegetation are often sparse, except for a thick layer of mosses or ferns in many places. Species are few and large tracts of forest may consist almost entirely of one or two species. Three sub-biomes of the coniferous forest were evaluated during the course of this study. They are described below.

Southern Pine Forest (Fsp)

The Southern Pine Forest consists of a number of different pine species. It is found in the sandy soils comprising much of the coastal fringe of the southeastern US. It is a specialized vegetation type thriving on fast-draining soils and frequent fires. The incidence of fire plays a major role in the stratification of the forest. Undergrowth can range from very thick in areas where fire has significantly opened the canopy to sparse in areas untouched by fire.

Coastal Forest (Fc)

This forest is found in the coastal regions of southeastern Alaska, western Canada, and the northwestern US. Under a heavy regimen of rainfall and prevailing high humidity, these areas have the densest of all coniferous forests. Coastal Redwood, Sequoia, and Douglas Fir predominate and are remarkable in their size and girth. Individual trees can attain heights over 100 meters and girths of over 20 meters. Although canopy closures average over 80 percent, high moisture budgets may result in a thick understory of ferns and mosses. These are especially prevalent on the myriad deadfall often littering the forest floor.

Boreal and Mixed Deciduous/Boreal Forest (Fbo/Fbd)

Boreal forest predominates in two great continental belts, one in North America and one in Eurasia between the latitudes of 45 and 75 degrees. It is predominantly composed of evergreen conifers such as spruce, fir, and pine. Deciduous trees such as aspen, poplar, willow, and birch tend to take over rapidly in stream beds or open areas and in portions of the boreal forest which have been burned. These open areas may have a well-developed shrub and/or moss layer. Mixed forest is common in the transition zones between the midlatitude and northern forest types and occurs partly in response to a cool summer season.

Midlatitude Deciduous Forest (Fd)

Midlatitude Forests are dominated by tall, broadleaf trees typically providing a continuous and dense canopy in summer, but shedding their leaves completely in the winter. Lower layers of small trees and shrubs are weakly developed. Predominant species are oak, beech, birch, and elm. Undergrowth is usually thick early in the growing season but is later reduced depending on the amount of tree foliage and subsequent shade. Undergrowth may be much more prominent in poorly drained areas and conifers readily develop as dense second growth vegetation once deciduous forests have been cleared. The deciduous forest is almost entirely limited to the midlatitude landmasses of the northern hemisphere.

World Vegetative Sub-Biomes by Continent and Country

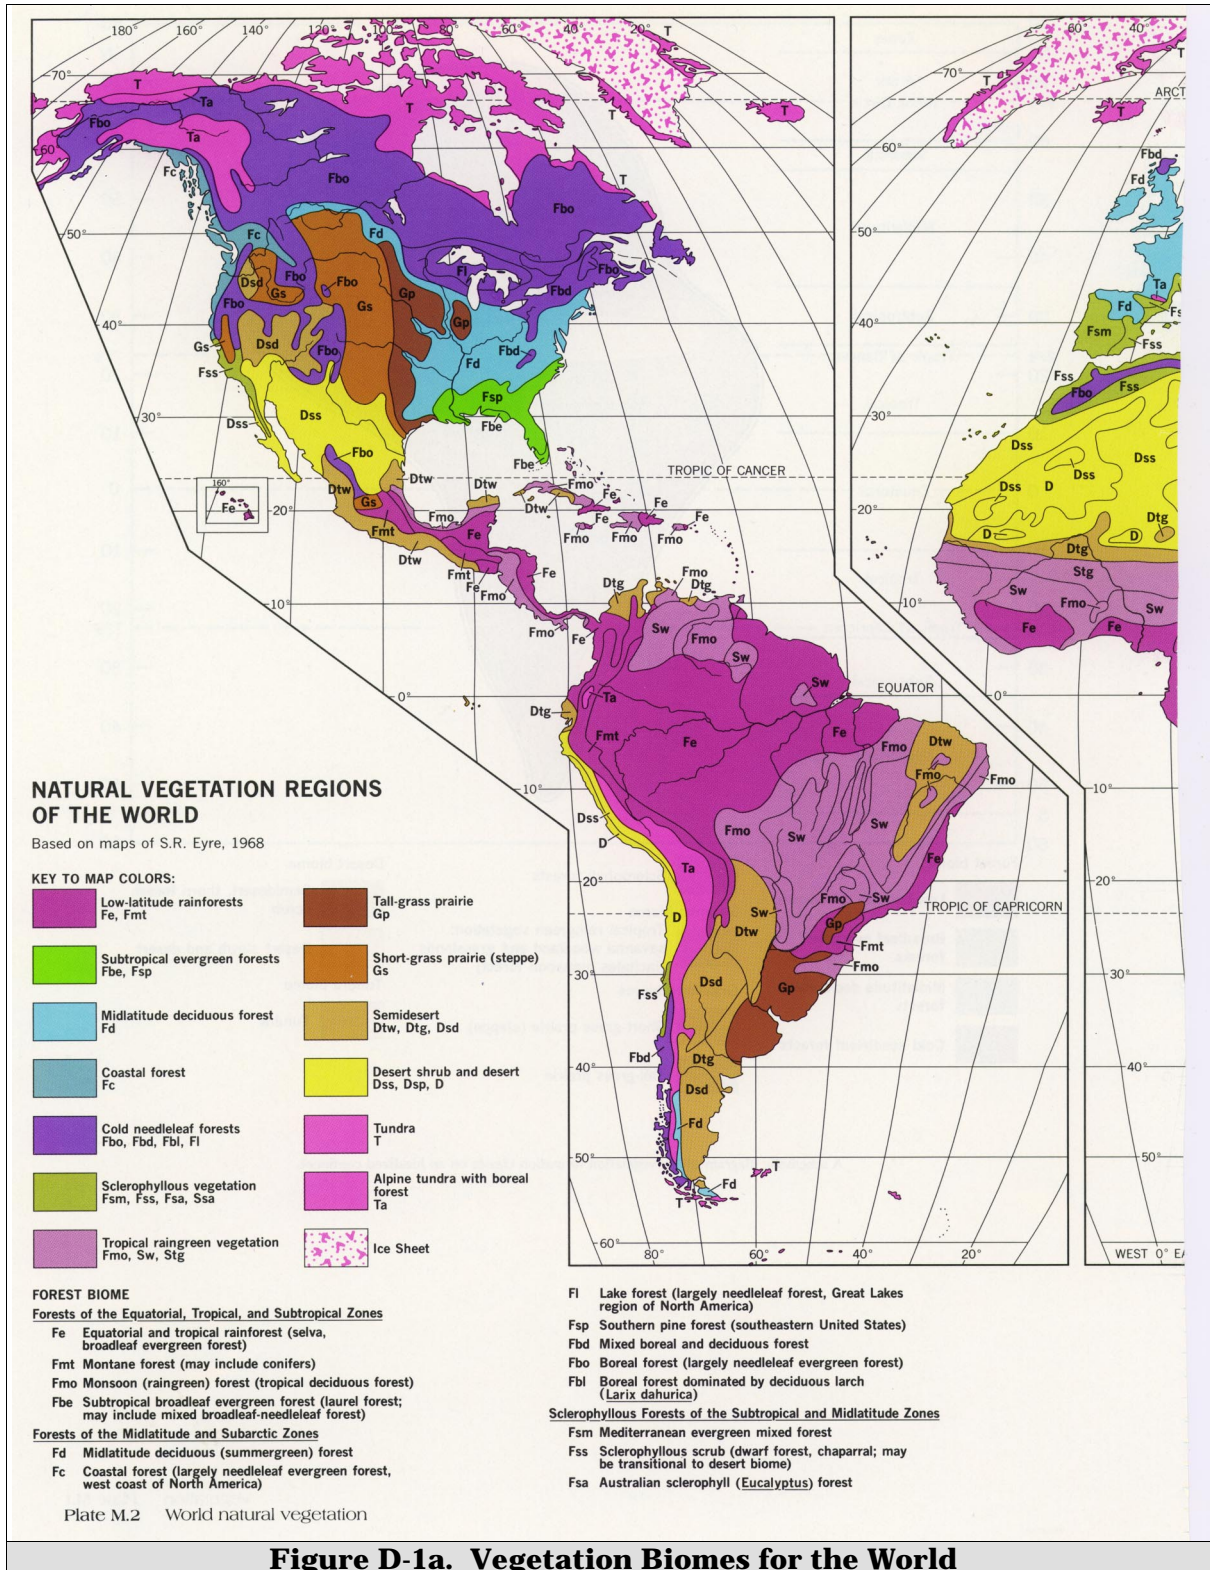

Figure D-1a. Vegetation Biomes for the World

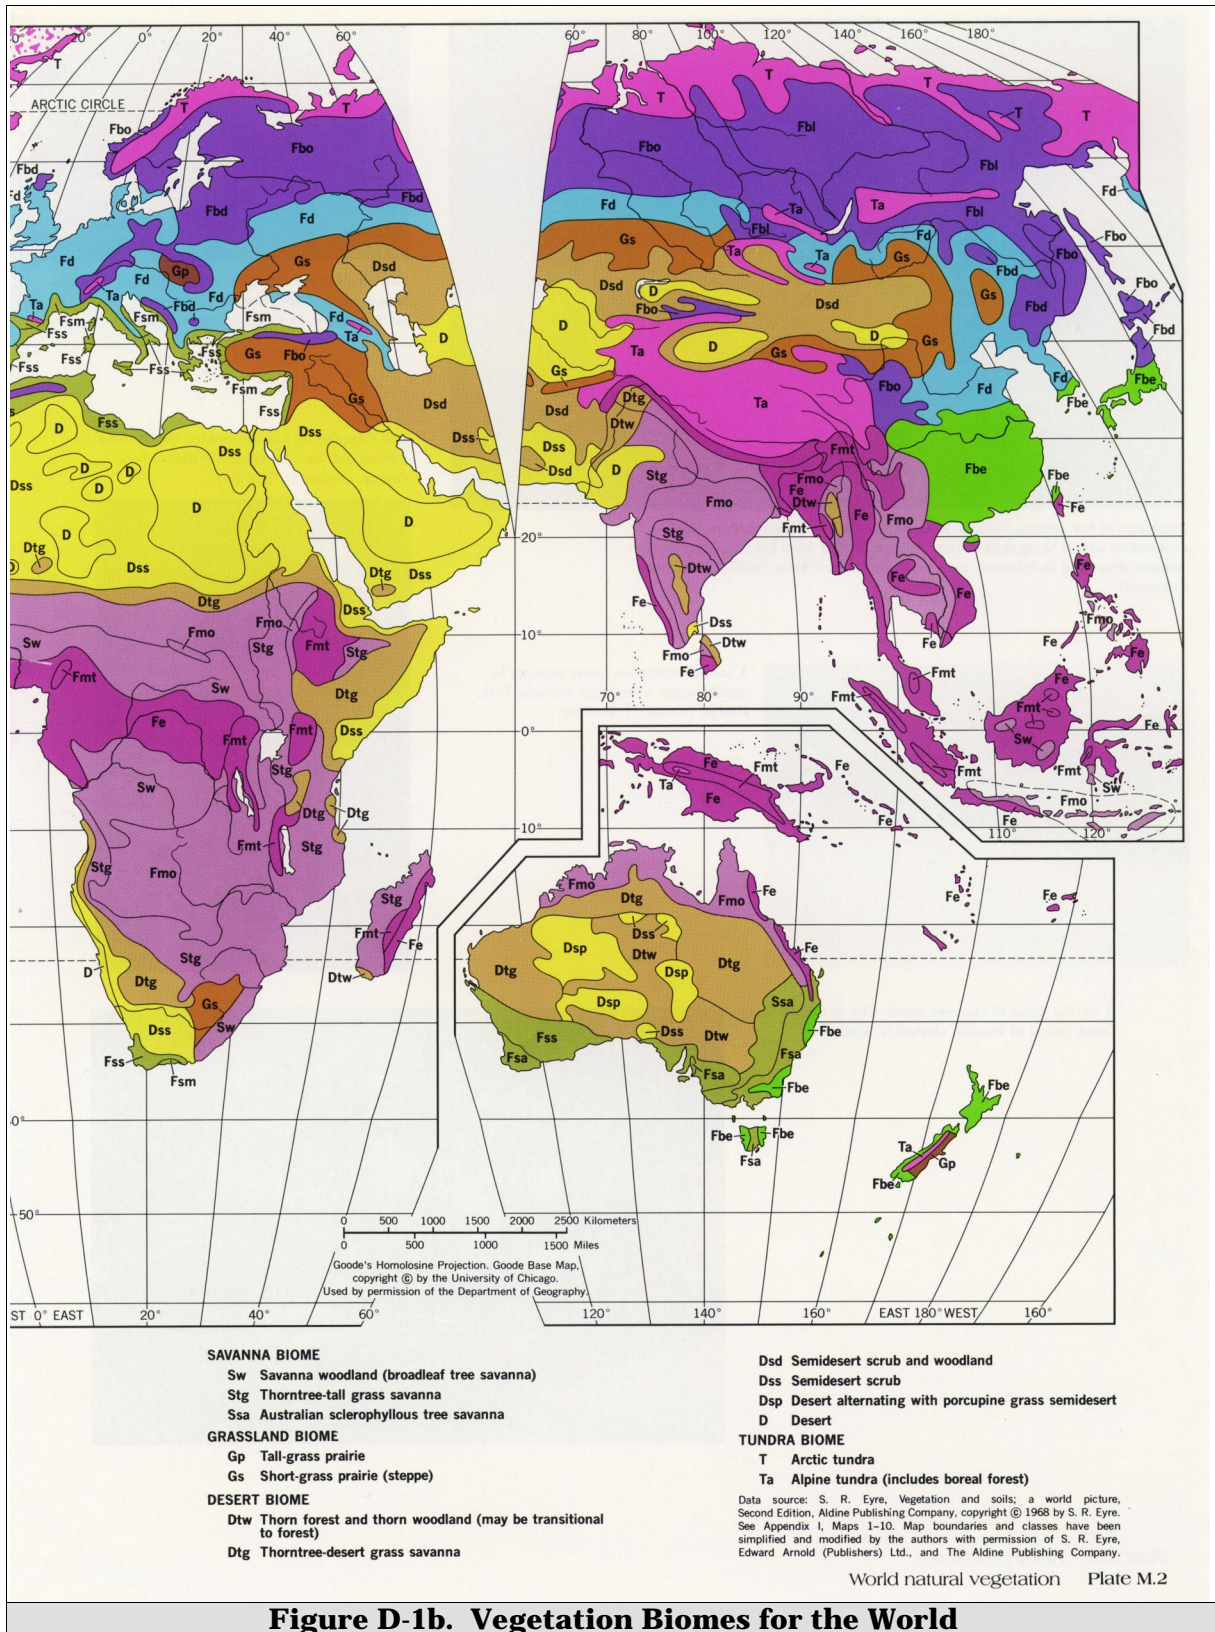

Figure D-1b. Vegetation Biomes for the World

key: (* - not evaluated in study; **represented in study**)

D – Desert*
Dsd – Semidesert scrub and woodland*
Dsp – Desert alternating with grass semidesert*
Dss – Semidesert scrub*
Dtg – Thorn tree-desert grass savanna*
Dtw – Thorn forest and woodland (transitional to forest)*
Fbd – Mixed boreal and deciduous forest
Fbe – Subtropical broadleaf evergreen forest
Fbo/Fbl – Boreal forest/Boreal forest (larch dominant)
Fc – Coastal forest
Fd – Midlatitude deciduous forest
Fe – Tropical rainforest
Fl – Lake forest*
Fmo – Monsoon forest
Fmt – Montane forest
Fsa – Australian eucalyptus forest*
Fsm – Mediterranean evergreen mixed forest*
Fsp – Southern pine forest
Fss – Sclerophyllous scrub (dwarf forest/chaparral)
Gp – Tall-grass prairie
Gs – Short-grass prairie (steppe)
Ssa – Australian Sclerophyllous tree savanna*
Stg – Thorn tree-tall grass savanna*
Sw – Savanna woodland*
T – Arctic tundra*
Ta – Alpine tundra (includes boreal forest); also known as taiga

The following biomes were not evaluated because of lack of vegetation: D, Dsd, Dss, Dsp, and T. The Fl and Fbl were not evaluated because they exist in unique areas (the Great Lakes area and northern Siberia) where the US Army is unlikely to deploy soldiers. The remainder of the unevaluated areas exist only in OCONUS and were not evaluated because of cost.

Appendix E. Analysis

Introduction

Fifteen diverse geographic locations were selected for data collection. They represent a variety of vegetative sub-biomes, climates, latitudes, elevations, and therefore a variety of vegetation densities. At each geographic location, several (usually four) sites were selected for data collection. Table E-1 describes the geographic locations, the individual sites, the grid coordinates, and the elevation of each site.

Appendix B provides a detailed description of the locations where data were collected.

Table E-1. Exact Locations of Field Collection Sites Including Easting, Northing, and Elevation

Raw Data

Figures E-1 through E-124 (provided at the end of this appendix) provide a visual description of the raw data. Each figure show the raw data collected along each azimuth, the quartiles (the middle 50 percent of the data), and the median of the data. The analysis will focus on the median curve.

The defensive positions selected for the field survey were selected as typical prone defensive positions. Data were collected from a crouching defender and towards a prone and kneeling defender for comparison purposes only. There data are provided in tables, but are not discussed in the analysis.

A CD-ROM is provided with this report. The CD-ROM provides maps depicting the exact locations of the each data collection site. Also included are panoramas of every tactical field of view. These panoramas provide the user with a visual image of where data were collected.

Analysis

Introduction

The analysis focuses on the median curve because it represents the most realistic representation of visibility in the field. The mean of the data were not used because outliers could skew the entire curve. Data were collected to represent looking at a kneeling target and a prone target. The kneeling target was 0.4206 square meter and the prone target was 0.12325 square meter. The y-axis of these plots is based on weather the target viewed was kneeling or prone. For example, if 100 percent of a kneeling target was seen, 0.4206 square meter was visible and if 100 percent of the prone target was seen, 0.12325 square meter was visible. The presented size of the target (number of square meters visible) is used in the detection equations.

Curve Fits

The fits to three different curves were selected in this analysis to provide different approaches to represent the effects of vegetation on LOS. The three functions fitted to the raw data are exponential, a field exponential, and a pole-zero.

The exponential function takes the form:

$$\mathbf{f} = \mathbf{e}^{\frac{-\mathbf{R}}{\mathbf{b}}},$$

where \mathbf{f} is the visible fraction of the target, \mathbf{R} is the length of LOS, and \mathbf{b} is a parameter of the function. A smaller value for \mathbf{b} implies a steeper decay curve.

The field exponential equation takes the form:

$$\mathbf{f} = \mathbf{e}^{\frac{-\mathbf{R}-\mathbf{a}}{\mathbf{b}}},$$

where \mathbf{a} represents the range at which the curve begins the decay.

The pole-zero plot, an equation usually associated with the frequency response of electronic circuits was included in the analysis because often it was the best fit of the data. This was to be expected, as there are twice as many parameters as in the other equations. It takes the form

$$\mathbf{f} = \alpha \left[\frac{\delta^\gamma + \mathbf{R}^\gamma}{\epsilon^\gamma + \mathbf{R}^\gamma} \right],$$

where α is a scaling factor and δ represents the part of the curve where the decay is so gradual that it is insignificant. The ϵ parameter represents the range where the curve begins to turn downward. In other words, this is the distance where the target begins a significant degradation. The γ parameter, the exponent in the equation, is a measure of how quickly the signal degrades as range becomes larger than ϵ .

Tables E-2 through E-9 depict the data fits for the exponential fits based for all eight combinations of POV, attacker posture, and defender posture. Tables E-10 through E-17 depict the data fits for the field exponential fits and tables E-18 through E-25 depict the data fits for the pole-zero fits. Along with the fits is the sum of squares error for each fit.

Representative Data Sites

Data were collected at several (between one and six) sites at each location. The sites at each location were analyzed and a site representative of the biome was selected by examining three different factors. First, the undergrowth data collected at each location was examined. The sites were subjectively ranked based on the most representative undergrowth type, median undergrowth height, and maximum undergrowth height. Second, the raw data curves along with the field notes were examined and the sites were subjectively ranked based on how well the site represented the location. Some of the sites were eliminated by this analysis because they were classified as outliers. Lastly, the data parameters for all three curves were examined and ranked based on parameters and sum of squares (a measure of error between the raw and the fitted data). Sites were ranked and preference given to those with parameters similar to the rest of the sites. The sum of squares was used as a discriminating factor when ranking sites with similar parameters. The most representative site at each location was selected based on these three approaches and presented in table E-26.

Table E-26. Best Representative Sites for Each Location	
Location	Site
Panama – Gamboa	gam2
Panama – Fort Sherman	mck1
Panama – El Valle	elv1
Eglin AFB	egl_B2
Fort Hood	hood1
Fort Carson	car28
Fort Hunter-Liggett	hl10
Fort Lewis	lew8
Fort Benning	ben_T4
Smoky Mountains	TN2
Willow Grove NAS	WG2
Natchaug State Forest	Nat4
Fort Drum	7G
Canada - Gagetown	Gage 31
Fort Greely	G2

Panama Discussion

Data was collected from Panama twice. The first data collection coincided with the end of the worst drought in over 100 years. Because the vegetation appeared dry and sparse during the first data collection, data was collected a second time at the end of Panama's rainy season. Surprisingly, the visibility during the two trips was virtually equal. The differences in the fitted curves for the El Valle site for the two trips are less than 1 percent across all ranges. The vegetation parameters for the sites at Gamboa and Fort Sherman indicate that the vegetation was slightly denser the second trip. However, the difference was undistinguishable by the data collection team and was apparent only after the data was analyzed and plotted. The analysis showed that for the two visits, the difference between corresponding best fit curves, for any given range, was always less than 5 percent.
